If you need some ST software may I suggest sending four disks to the address

below. I will copy the following items plus others onto those disks:

Utilities: Mike's RAMDISK, other RAMDISKS, uuencode/uudecode,
    stsqueeze/unsqueeze, microemacs, CLI, xmodem/vt52 emulator, disk/memory
    editors, disassembler (barely), 410K/820K disk formater etc.

Languages: Bradley's FORTHMACS, XLISP, ASSEMBLER, PROLOG (ontop of XLISP)

FONTS: about 30 (only work with TOS.IMG on a boot disk)

Sources: XLISP and XMODEM C sources

Docs: Disassembler, microemacs, cli, xlisp, forth, assembler + others

Accessories: Clock, RAMSIZE, RAMDISKs, cli, directory print + others

John Franco
2535 Spicewood Lane
Bloomington, IN 47401
USA

Be sure to include a SASE, packing material
and four disks formated SS.

Now that I've solved the problem of LIBF (the modules are all in the
wrong order), I thought I'd rearrange the modules so that they can reference
each other properly. So I used the command:
AR68 xv libf
with no modules listed after "libf". This is supposed to cause AR68 to
produce copies of all the modules of libf into "the default drive".
The result, however, was a syntax error diagnostic. And this is a

correct diagnosis. The TOS manual (really CP/M-68k) with the dev kit
on page 7-7 specifies a syntax which is illegal.
        So what is the correct way to do it?? Anybody know?

        Secondly, since there is no documentation on NM68 in the manual,
does anybody know where I can find this documentation?
        Thanks in advance, ...Alan Kennington.

This is, I believe, the last file missing from the earlier versions of
the STarter Kit that I will have to post for people needing it. It is the
documentation for the CLI accessory. It is rather short so I hope no one
thinks this is a serious abuse of the net.

------------------------cut here---------------------------
    A very simple command line interface for the Atari 520ST TOS.

    Syntax is a VERY small subset of the Bourne shell supplied with
    the Unix operating system. Specifically:

     Each command is a seperate line.
     Each command consists of several words separated by white space.
     The first word is the command name.
     If a word matches "name=value" for some name and value, it is
         variable assignment and not considered part of the command
         line.
     A dollar sign followed by a variable name is replaced by the
         value of the variable.
     Single quotes protect characters from all interpretation.
     Double quotes protect characters from all interpretation EXCEPT
         for variable replacement.
     '*' and '?' wild card characters are supported, but only in the

```
        "leaf" part of the filename.
    Input and output redirection is supported to and from disk files.
    The only variables with special meaning are:
        PATH command search path
        SUFFIXES  supported command types
      The elements in the PATH and SUFFIXES list are separated
      by commas.
    The only built-in commands are:
        .         temporarily read commands from file
        cd        change directory
        echo  print arguments on screen
        meminfo   print some memory usage info; mainly for debugging
        pwd       print name of current directory
        set       list defined variables
         -v   print lines as they are read
         -x   print lines as they are executed
        version   print CLI and GEMDOS versions
   Control-D exits from the program.

Keywords: how do you get it to compile?

Has anybody succeeded in getting the MicroEmacs V30 (posted to mod.sources
last month) to run on an Atari ST?  I get warning messages like "pointer
subtraction yields a long result" while compiling display.c, and then the
linker dies with a seek error while trying to load display.o.  This is
with the developer's kit C compiler and using the .bat files supplied
with the microemacs sources.  I see some comments in the code at the
relevant places in display.c referring to "Alcyon C hack", but I'm not
enough of a C wizard to figure out exactly what's wrong or how to fix it.
(Pointer arithmetic?  Blecchhh!)  Can anyone enlighten me?

This conference suffers from (1) entries getting submitted in duplicate
or triplicate, sometimes over a period of three weeks; (2) excessive
quoting of previous messages in letters that really don't add much; and
(3) too goddamned many header lines in each message; that "fix your mailer"

line is especially redundant.
The conference info-ibmpc suffers from none of these, probably because it
has a moderator (the job rotates weekly, I believe).
Short of getting a moderator, the best thing that could happen would be for
info-atari16 to get filtered through a program that filtered out old
or empty messages BEFORE they are sent out to us listeners.
--> Do such programs already exist?

Yes, Hitachi is making a CMOS 68000, named the HD68HC000; it sucks less than
35 mA at 12.5 MHz (according to a Preliminary data sheet dated Sept. 1985).
The data sheet looks exactly like the 68000 data sheet, as far as I can see.
The dude I talked to says they've been waiting forever for permission from
Motorola to come out with this part, and finally got it after Motorola got
the 68020 out.

The most recent DEC redistribution, as modified at Caltech for blinding
update speed under NANSI.SYS or FANSI, as well as the most recent Daniel
Lawrence redistribution (3.6), are available for remote FTP as follows:
machine: tybalt.caltech.edu
account: anonymous
for DEC version, cd to pub/uemacs36c, mget *.*
for Lawrence version, cd to pub/uemacs36d, mget *   (I meant * above, too)
- Dan
p.s. Lawrence MicroEmacs 3.6 has an impressive list of features, but
     is amusingly slow at handling input when compiled under Large model
     of Microsoft C.

Oh brother!!! What else will you 'get serverly annoyed at'? Look buddy
CBM paid for their machine. They pay for the phone line that connects it
to the net. Andy (and John) are welcome to voice their opinion. Did it
ever occur to you that in *THIS* case Andy was simply expressing his
opinion. Andy.. always make it clear that it's YOUR opinion not CBM's.

I personally believe Andy is right and welcome ANYONES opinion on ANY
subject that is pertinent to the net or the new groups on the net. Atari
, C-A, MIPS, and 1000's of other employee's of companies have voiced their
'opinions' right here on the net. You figure the guy that posted the
original note did so from his personal U**X machine? Maybe, but odds are
against it.

John, went a bit overboard in his flame (probably a reaction from being
nicer in his personal life 8->). But yours! Well ... I guess you've
never used the net to voice your opinion from a 'for-profit' company or
a for-profit institutional machine. Gee a *REAL* saint! 8^)

1040s have a heat problem, reported in one case to cause sagging of the
plastic case. They also have a disk drive reliability problem, said to be
possibly due to the heat problem.

520s can be upgraded but the MMU has been alleged to not have enough drive
capability, thus requiring resistor "fixes" to protect it or something. Other
sources say it is the power supply that is the culprit, not having enough
current capacity and thus causing various components to operate at the wrong
voltage.

Sounds to me as though an upgraded 520ST with a better-grade external power
supply might be the way to go. 5-volt DC supplies of good quality are widely
available or can be built at fairly low cost. I think if I were buying right
now it would be this approach.

Down with little black transformers all over the place! The time for REAL power supplies has come! (What voltage/current do the monitor and disk drive require, while we are at it?)

The modem I bought was by Avatex, not Avantek. It sells for under $100.
I paid $80, and others can possibly get that price or better in a group purchase. Call Rick Pommet at Nelson Communications, (617) 738-6000 to strike up a deal. (He is a died-in-the-wool Atari freak, so he is sympathetic rather than greedy!)

Summary: Should binaries and sources for non-UNIX machines be on th net?
Xref: decwrl net.micro.atari16:775 net.mail:1623

.
So what is the verdict?? Is the posting of sources and binaries for the ST kosher? Or is the net only around for UNIX and like systems? If it is, how are the following newsgroups justified?

net.sources.mac
mod.amiga.sources
mod.amiga.binaries

I for one, use many machines (IBM,SMI,DEC,Atari,Apple,Motorola,etc.) at work, and most of them are not UNIX machines. I appreciate getting useful programs for these machines from the net. If I have to, I will call a BBS to get certain useful programs, but I prefer not to, when: A) UCSD (my place of employ) should be paying for the acquisition, B) it is annoying to stay up until 1 AM, only to get 20 minutes of access to a busy BBS, and C) my VAX has uucp, which does it all so much better.

I had always suspected the net was around for the exchange of software and related dialogue. I had no idea I would get flamed for suggesting it continue. Please reply with intellegence this time, but if you really have to flame, mail it to me, don't post it.

I am having some problems with a program designed to read/write the rs232, whilst accessing the floppy disc. I would appreciate any insight, hopefully from people who *know*. The program uses Caux...() calls to access the rs232 line, checking for availability of characters/buffer space etc. & using stdio for disc i/o. The problem arises when transferring data from the disc, whilst receiving from the rs232. This is the only combination that presents problems, the program will happilly receive lots of input from the line, or send lots of data to it, but when trying to do both, it locks up. A logic analyser shows the cpu to be constantly in supervisor mode, with no excursions whatsoever back to my program. As best as I can tell, the code being executed is related to the video sync interrupts, but it is difficult to be sure. I have no idea how it achieves this state, the keyboard & mouse are both locked, and the only recovery is to reboot. The activities are all intended to be synchronised by an evnt_multi(), with the rs232 i/o kicked for each event (a timer event is included just to make sure it happens) and the file access kicked whenever there is nothing better to do (eg when the timer event actually occurs & no rs232 i/o is needed).

4. And Search Rules for the compiler! Do they exist? I hate putting absolute pathnames in my sources, but hate moby folders that take the whole screen even more.

5. If anybody has a Copy.TTP and/or Move.TTP, please post them. Perhaps they exist in some repository which I haven't found. Or I could just write them, but ...

6. It seems that Application Document types are known system-wide, but the application handlers themselves must be in the current folder. Also, I often want one application handler (e.g. micro-emacs) be in effect for multiple document types (e.g. source.c and source.s).

7. Is there an option to save the desktop before an application starts so that exiting the application and returning to the desk wouldn't involve spinning the disk? Perhaps pickey, but it takes a few seconds and happens quite often. Perhaps the Moby RAMDISK is the way out.

8. My friend made me extremely gealous over lunch the other day quoting how his Thinkware C on a MAC+ did a compile-bind-go in 10 seconds. I'm struggeling with a 90 second compile and a 5 minute load using the developers kit. (I guess GEM libraries are big.) I know that both are about 5x faster using RAMDISK, but I need more memory on my 520 to fit everything.

9. My warantee will be up in a month, and I'm going to get the old soldering iron out. Does anybody have any experience with putting in 1M chips? Does the ST's MMU handle them? (it seems to have pins enough, what about refresh? (Neil?)) I believe it would require flying wires on a few address lines, but no piggybacking. The thought of doing compiles and links from a 1.5M RAMDISK really turns me on!

10. I'm looking for a set of graphics primitives that will make porting my pet children's game to other PC's as well as the ST easy. Does GEM foot that bill? How stiff would lisence fees be for customers who didn't already have GEM, given the package wouldn't expose bare GEM functionality to the user. Anybody know of other packages or conventions that work?

11. Boy, would I like to have a copy of Switcher to go quickly between contexts quickly. What I'd really rather have is multiprocess windows like the Sun, but lets be realistic! Two practical questions though: Is it possible to bring up a GEM application on the same desktop as (using MAC terms) the finder? and Does GEM support any sort of multi-tasking? Does any one out there have any hints?

DOES anybody know if someone is developing a networking or shared-peripheral system for the STs? Seems to me they'd make darn good classroom use computers (better and jsut as cheap as Apple, probably) if Atari would take the education market seriously. Anything that would enable 16 or so STs to share a common printer and hard disk or tap into a mainframe would sure help.

Also, anyone know how to set up a printer driver for the Mannesman-Tally Spirit 80? It is not Epsonable, it seems.

HELP! I have been experiencing a problem using the VT52 emulator on
my 520ST. While connected via modem to a vax with unix I have problems
while using the vi editor. It seems to have a scrolling problem when
the lines are around 65 or more characters long.

I don't think that it's an emulator bug because the same thing happens
while using CHAT. I have tried using several termcaps that have come
over the net as well. Maybe I need to perform some unix shell command?

Has anybody else had this problem? If so, do you know of any solutions?

  The MicroEmacs files I mentioned at tybalt.caltech.edu are C source files.
  In the DEC version in pub/uemacs36c, the files starting with pc_ are MS-DOS
  specific; those starting with at_ are atari specific.
  The Lawrence version in pub/uemacs36d is fresh out of the box and unmodified;
  its system dependancies are handled with #if preprocessor statements instead
  of separate files.

I've been experiencing a problem with the desktop VT52 emulator on a
fairly regular basis, and I'm wondering if I'm the only one. What happens
is this: some noise comes over the phone line (like when it hangs up on
the other end), and suddenly the terminal emulator goes dead. Nothing
shows up on the screen, nothing goes out the RS232 port. Going back
to the desktop and then back into the terminal emulator doesn't do a thing
to unwedge it; you have to hit the reset button. My modem (a Signalman)
is admittedly not the most reliable piece of equipment in the world, but
I've never had similar problems using it with my Heathkit terminal. Does
this sound familiar to anybody? Is there some less catastrophic way to
unwedge things?

On the subject of the high frequency noise from the 1040:
Mine HAS a noise from the disk drive (internal). There is no other noise that shouldn't be there (within my normal hearing range). I get a high frequency noise from the intyernal disk drive every time I turn on the external disk drive. It is clearly caused by resonance of soime loose part of the drive mechanism, which is only free to vibrate when the drvie is not actually reading or writing.

A piece of loose metal rings like a bell most times when the external drive just starts up.

So it looks as though there is some variety in the 1040 noises.

So long, Alan Kennington.

Summary: 1040 overheats? Not mine!

I've had my 1040 on for hours at a time, and not noticed either the machine overheating or the disk becoming unreliable. Of course, my machine's still under warranty, so I shouldn't expect that sort of problem.

Well, the simple solution was to order a replacement power supply,
which is only $40CDN.

I opened up my old power supply to take a look at the problem, and I
was *not* impressed. About 2/5 of the supply consists of a large
transformer in a sea of wax. The main PC board was held into place
by a foam rubber "stopper". The problem -- two of the large diodes
(part of a bridge rectifier) had exploded, leaving diode bits and
a blackened PC board. I was very lucky it didn't take the ST with it...

I have a feeling quality control consists of "plug it in, if it works, ship it".

Those of you with the old style power supplies might do well to
buy one of the newer supplies (disclaimer -- I haven't been inside
one of the new ones -- it might be just as bad), since they're only
a small fraction of the price of your ST system.

I've had the same problem, and I don't think it is related to the VT52 emulator itself since the same thing has happened while using the xmodem program emulator as well as with the desktop emulator. I'll have finished a call and want to dial another, but the ATDP 1234567 does not echo on the screen. Turning the modem off and on does nothing, so I have to hit the reset. I'm using a Volks 12 and 520ST. Does anybody in net.land know what's going on here??

As part of a Psychology experiment at York University, a subject
will be given an st (running DEGAS) to play with. The session must
be recorded (what functions were used, what was drawn, etc.) for later
study. Ideally a video recorder would be attached to the display and
recorded for later study, or failing this, the keystrokes/mouse actions
might be recorded.   So..

(1) Has anyone attached a vcr to the video-out on the st to record the
    display? Is it possible to convert the video-out signal to
    composite video? (and no, the st does not have a composite out jack).
(2) Is it possible to record all user actions in DEGAS?

I'm not sure about the Hitachi parts, that's a rumor that has been going
around. There's no difference in spec, but possibly some internal/timing
differences. Anyway, Motorola itself has just announced a CMOS 68000, and
its coming out at a low price, unlike the usualy Motorola introductions.

> otherwise it is ignored

A quick check of an ASCII chart reveals that 0x12 is NOT the XON code.
XON and XOFF are (respectively) 0x11 (^Q) and 0x13 (^S). The 0x12 code
has the name DC2 in the ASCII chart. Regardless, why would the BBS be
telling me XON in the first place? It never told me to stop (XOFF).

If my memory serves me well, the DC1-4 codes were originally intended
to be device-specific control codes, hence "DCx" (Device Control).
Further, I seem to remember (from Teletype days) that two of the DC
functions were "PUNCH ON" and "PUNCH OFF".

Anyway, back to the original question. Why is the BBS sending the
0x12?

Yes indeed,
     As I understand the situation at the end of this year/start of next
a new machine - the EST - will become available. This has the 68020, a blitter
and a better graphics chip giving 4096 colour pallette.
     It will run all properley written ST software, and proberbly be
supplied with unix as well. (unix would not work well on just the 68000 without
a lot more memory and hard disk)

Atari does supply a diagnostic kit, but ONLY to authorized service centers.
The kit includes a module which plugs into the cartridge port of the ST and
which has a separate RS232 port for a terminal or another ST. Diagnostics
are performed through the other computer.

Atari does not officially support or endorse upgrades to the ST.

My personal opinion (and NOT that of Atari Corp) is that if you upgrade
your machine, you'd better be friendly with an authorized service center.

From the rock'n'roll capital of the world --

Here's the final tally on 1040ST reliability. We took delivery on
twelve machines. ALL twelve 1040's came up with no problems. NONE
of the machines are overheating. A FEW of the machines generate
enough switching supply noise to be annoying. ONE of the monitors
arrived damaged -- the only DOA -- and probably due to mishandling.
(Some glass shards were found at the bottom of the plastic bag and
the tube "looks wierd.")

This is not to say that some folks are hallucinating their problems.
However, the occurrence of the overheat or disk drive problems may
only apply to a statistically small number of units and should not be
overhyped. I am sympathetic to the individuals with these problems
and hope that Atari (or whom ever) will help them out PRONTO!

There is an outfit in San Francisco that can take a disk with NEO files
and make color separations or black and white stats. For color work they
charge about $125, for b/w much less. The quality is excellent -- look at
the screen shots in Atari's recent ads.

The company is called Imageset, and they're in the SF phone book.

By the way, they can do the work in ANY resolution using NEO files created
by the SNAPSHOT utility which is floating around (it's on the Atari BBS
at 408-745-5308 if you can't find it elsewhere).

The best way to download from Atari Base BBS is to use Xmodem, which in PC/Intercomm is called "Modem7". Get to the point on the BBS where you have selected a file to download and it tells you to prepare for Xmodem download. Then go to the PC/Intercomm menu and start the download. It should work fine.

The other download method is DFT, which is a unique format that Michtron uses in their BBS software and in their terminal program, MI-Term.

Raw is the same as ASCII except that control characters are not tampered with. ASCII is useful only for text files (like the news files in the General SIG).

Hope this helps -- if you need me you can reach me by a note to Sysop on the Atari Base BBS.

I have had no end of trouble getting this baby to work. Could someone send me some working code that uses this routine. I must be doing something very wrong! The requester mode works and I am setting vsin_mode() or what ever it is called, to set the sample mode. But the cursor seems to be stuck at one location and cannot be moved.

Also I am getting two responses in the requester mode for both mouse button down and mouse button up. Can any one help me??????
thanks mucho...

Sure, let's let {ucbvax,ihnp4,akgua,hplabs,sdcsvax} pay so this guy can
play with his Atari. After all, he can't afford it, but they
can. In fact, why not just post the entire contents of the BBS to
the net -- then *everybody* can pay for the phone time.

This doesn't even rate a :v} because it's not funny.

Every morning I get up and say "why do I flame so much on the net when
I'm trying to be kinder in my personal life?" Every night I run into these
bozos though...

My dDad bought Micro Illustrator for his Radio Schachack PC clone, but later
found out the only printers they support are $1600 ink jet ones! This seemed
patently reidiculous to me, since the print fileimaag=age is stored on a file and
the format of the file mis known to some software. Why couldn't it be
sent to ainterpreted by a program and sent to a dot matrix printer. After all,
on a monochrome screen, it's only pixelss.

Can anyone tell me the format of the print file. ? I am assuming that
Micro PIllustrator files are compatible across systems (and that the
same is true of their print files).

What is the status of the IBM-PC Compatibility accessory I have heard rumored
for the ST -- is it now released? If so, what are the specs? What exactly
can it do and not do? Does it use the standard ST disk drives or provide
a new one (am I correct that the ST uses 3.5-inch drives and the PC uses
5.25)? Is there provision for transferring PC data files to Atari disks for
use with Atari programs (e.g. word processors)?

How much does it cost?

How "compatible" is it? How many card slots does it have left for expansion
when reasonably configured?

What other questions should I have asked and what are the answers? (That sort
of covers a lot, doesn't it?!)

Any assistance will be greatly appreciated.

I notice that sometimes GEM will draw a window full of text (using a
series of calls to vgtext) faster than at other times. Does anybody
know under what conditions this happens? General comments on using
text would also be very welcome.

Thanks in advance.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

About a month bammi@cwruecmp.UUCP posted a set of sources for PROFF, a
troff/nroff look-alike for the ST. In the instructions for building
PROFF he refers to a Micro C-shell and CC that he posted to the net at
some previous time. As I didn't see it go past I assume it expired
before I started taking an interest in the news. So, is there anyone
out there that can let me have a copy ??

Here's hoping...

[double-sided line-eater? - HA!]

Hi,

There has been some talk on this <net.micro.atari16> newsgroup about RF modulators on 520/1040 STs. I was a bit upset when I got my 1040 here in the UK, as it has no modulator or composite output. In fact, on the box it said 1040STFM, but the Ms had been carefully whited out all round the box. This was a particularly strong problem as, unlike all home computer mono monitors I had met until now, the Atari monitor does not even _try_ to do grey scales. This means that any software that requires a colour monitor will just not work - I still haven't even been able to start up the Neochrome program I got free. Is this really just a sneaky way for Atari to get people to buy their (admittedly good, but expensive) colour monitor, or is there some technical reason?

What I would really like to know is can anyone help me with a circuit or a cheap source for a ST-RGB/PAL-RF modulator. All help appreciated. If anyone else is interested, let me know, and I'll summarise to the net.

Cheers,
Frank.

Here is a First Word configuration file for the DEC Letterprinter
100 terminal. Other letterprinter users may like to have this
because the printer is quite different from the EPSON standard.

-Brian

```
------------------------------------------------------------------
******************************************************************
*
*    DEC Letterprinter 100 Matrix Printer Driver Configuration Table
*
*
*    This file contains tables defining the code sequences
*    to be sent to the printer to perform various functions
*    and to access the characters from codes in the Atari
*    character set.
*
*    These codes do not initialize the margins, spacing,
*    page length, character set, transmission mode, etc. of
*    the letterprinter.  Also, they assume a standard character
*    set in G0 and the DEC Technical character set in G1. The
```

```
*    special symbols will not print properly without the DEC
*    Technical characters.  Also, note that superscript and
*    subscript work poorly with the tractor feed option.
*
*    This file was created by Brian Bray using the sample files
*    supplied with First Word (86/05/08).
*
*****************************************************************

*
* Name of printer
* ===============
*
DEC LP100

*
* Miscellaneous configurable variables
* ====================================
*
* 1: printer type, 0=dot matrix, 1=daisy wheel
*    Note if printer type is 0 the following 4 variables are never used.
* 2: unit width of one character
* 3: unit height of one line
* 4: Approximate middle of carriage after formfeed
* 5: Carriage shift for bold overstrike
* 6: 1 to pause between pages
*
0, 0, 0, 0, 0, 0

*
* Printer characteristics
* =======================
*
* This table specifies the printer command sequences.
* If the top bit of a code is set, then this indicates the position
* of a parameter passed to the printer. The code whose top bit is set
* in this table is added to the parameter passed before being sent to the
* printer. It is not used in all command sequences, only in those where
* the printer requires  a variable value such as the length of a vertical
* tab.
*
* 0                                 * Character width
1, D, A                             * Linefeed WITH return
* 2                                 * Forward print
* 3                                 * Reverse print
* 4                                 * Vertical tab to line (FX or LX)
* 5                                 * Absolute horizontal tab

1D, 1B, 5B, 30, 6D                     * NLQ underline off
1E, C                              * Formfeed
* 1F, 12                           * Horizontal initialisation
* 20                               * Vertical initialisation
* 21                               * Termination
0                                  * NULL termination byte

*
* Translation Table
* =================
*
* This table provides translation from single Atari input bytes into
* multiple printer codes, and is useful for printing extraneous
* characters such as accented characters etc. All characters are
* subjected to translation, but if there is no entry in the table for
* a particular code, then the original code is sent to the printer.
*
* The entries must be arranged in ascending order of Atari input
* code. The table is NULL terminated.
*

0                       * NULL: print a space
1, E, 7C, F             * Up arrow: USA | backspace USA ^

Here a driver for First Word with the Smith-Corona TP-1
daisy wheel printer and the "Presidential" and "Ascii"
type wheels. It took some fiddling to get this to work,
so posting should save others time.

-Brian

```
------------------Start of File---------------------------------
*****************************************************************
*
*    Printer Driver Configuration Table
*
*    for Smith Corona TP-1 printer.
*
*    This file contains tables defining the code sequences
*    to be sent to the printer to perform various functions
*    and to access the characters from codes in the Atari
*    character set.
*
*
*    Usage:
*
*    This printer has been declared as a "dot matrix" because
*    it is too dumb to recognize the codes sent by 1st_prnt
*    for daisy wheels.  In order to access both a dot matrix and this
*    driver, rename the file 1st_prnt.dot to 1st_prnt.dsy after
*    running the configuration program on this file.
*
*    This file was created by Brian Bray from sample files
*    supplied with First Word (86/05/08).
*
*

*
* Translation Table
* =================
*
* This table provides translation from single Atari input bytes into
* multiple printer codes, and is useful for printing extraneous
* characters such as accented characters etc. All characters are
* subjected to translation, but if there is no entry in the table for
* a particular code, then the original code is sent to the printer.
*
* The entries must be arranged in ascending order of Atari input
* code. The table is NULL terminated.
*

0               * NULL: print a space
1               * Up arrow

>expect that GEM may have the best chance.  Why?  You can get off the
>shelf applications for GEM of the sort that most people are interested in.

Funny, the only GEM-68K stuff I've seen is the stuff written for the ST.
```

I agree that the GEM part of GEMDOS could be a good "upper level" interface, but GEM can be put over a number of other operating systems such as MS-DOS, CP/M-86, CP/M-68K, and GEMDOS, why not OS-9? GEM makes a good supplement to any other OS, but that other OS does not HAVE to be GEMDOS.

Also, I have discovered that Micro-Ware also has a VDI for OS-9, supporting bitmapped systems or CRTC type devices such as the 7220 or 63484. My main reason for suggesting that OS-9 would be the FIRST contender is that it is already available, and people are doing the ports now. Other candidates might be better, but OS-9 is so easy to port.

>Languages are not applications. Spreadsheets, Word processors, painting
>packages, DBMS programs, games, THOSE are applications.

How about things like Tandy's Desk-mate? There are a number of applications which were written for OS-9 (6809/CoCo) that could easily be ported to OS-9 68K. Many of these are even in public domain.

>People want to buy
>PeeCee DOS emulators for their machine, NOT OS-9, and certainly NOT because
>PeeCee DOS is a better OS.

Actually, I'd rather see a PC-DOS -> 68K translator. Even the emulators are painfully slow. Besides, there are no real graphics STANDARDS for PeeCee DOS. Which cards to you emulate, how do you keep the application from "Capturing" a multi-tasking operating system. You don't!

>GEM is not owned by one of the hardware
>manufacturers, who would probably want to keep you locked in to their
>hardware and not let their OS run on other machines.

Neither is OS-9, in fact, the port is also being done by a third party who is doing the port for all three machines.

>This is what will rule
>the MAC OS out. TRIPOS would only have a chance if Amiga would consider
>selling Intuition (their graphics/windowing software) to go with TRIPOS.

I agree in part, actually, Metacompco (sp?) wrote most of the graphics package, Amiga had to write the "Graphics BIOS", or drivers.

>This would actually be in Amiga's best interest, TRIPOS and INTUITION running
>on a ST would sell a lot of Amigas, both by expanding the attractiveness to
>developers of developing Amiga compatible packages, and by magnifying the
>performance and feature differences of Amigas vs STs.

Actually, it would work well for BOTH companies. Those who wanted the extra performance and features, and could afford it, would buy the Amiga. Those who needed a less expensive machine for taking their work home at night, could buy the ST. If both machines could run the same applications, you wouldn't have sheer numbers of ST owners trying to get their companies to go with the lower performance machines. Look at the Apple II vs. C-64 problems in the schools. Most schools have Apple II's, many parents have

C-64's because they are cheap. When teachers start assigning "Apple-only" home-work, parents get upset. The end result, "computer home-work" cannot be assigned. If parents were given a "vote" on the computers that schools purchased, Apple would probably NOT be the winner.

>Otherwise, TRIPOS
>has the same problems as OS-9. GNU might have a chance, because it's free.
>There is no way I am going to BUY an OS for my machine even if it is a great
>OS, if there are no (or almost no) applications that run under it. If it's
>a FREE OS, (public domain or similar) THEN I might be inspired to run it on
>my machine.

You mean you wouldn't pay $60 for an operating system if you knew that you could get several hundred applications off of Compuserve, net.sources, and hundreds of BBS's? You might still want to run Intuition or GEM at certain times, but you COULD run OS-9 to feed data into the other OS.

>If Atari, Amiga, Apple or some Alternate manufacturer produces
>a machine that comes with OS-9 plain vanilla, and developers decide to get
>behind it, then OS-9 has a chance. Until then, OS-9 is at the level of the
>8-bit CP/M systems, because there will be no applications that will use any
>graphics, windows, or other neat stuff that you need to sell applications
>these days. I don't need OS-9 to run 'C', assemblers, Modula, Pascal, Lisp,
>Basic, Forth, etc. on my Amiga, or to be able to print stuff while I'm
>editing or compiling now do I?

No, but if you have a 'C' compiler for OS-9, you will be have access to several hundred "free" programs. When you got them compiled, you could take the SAME FLOPPY, and plug it into the ST, the Amiga, and the MAC. You could even post the uuencoded binary, and we could ALL use the binary. In addition, because the libraries are so similar to UNIX, you could also compile most of what's in net.sources without modification. Again, you could post the binaries, share the floppies, ftp, and distribute, to anyone with any of the three machines, along with any others that might come out in the future. You can't even do THAT with UNIX (which trap/vector is to UNIX?, what are the DEFINES?, which "a.out" format is this?,...).

No, but if your company decides it wants to replace it's 1000 burned out VT-100's with ST's, you won't be able to do work at home either. As it is, your children can't "turn in a floppy" from your Amiga, because the schools only have Apples (which can be upgraded to accept OS-9 68K). If your child learns to use AppleWriter, that knowledge will be hard to practice on MacWrite, AmigaWrite, or even Micro-Emacs.

Appearantly, there is a little confusion here. Any OS is a collection of modules. Typically, you have the "drivers" or "BIOS" which convert hardware dependancies into a uniformly contollable format, usually something very simple, the "Kernal" which manages organization of storage, scheduling of tasks, and semaphores. In addition, there are often upper "layers" such as GEM which can use a graphical BIOS, and the OS. These "Graphical Operating Systems" also come in "layers". There is usually, the BIOS, which determines how to get objects displayed, the "Graphics Kernal" which lets graphics be put on the screen or even to disk for that matter, and

the VDI, which makes "widows, disks, and comm-lines" appear to the application to be "generic, self contained devices".

In other words, if I say circle(fd,x,y,r), to a VDI device, the call will be treated differently depending on which device "fd" describes. To a disk, it might just write tokens, or postscript text, to the disk file. To a window, it might draw what can be described in the window, or draw it off screen, and let another part of the kernal Bit-Blt the off screen image onto the "window". The principles are no different that those of UNIX, MS-DOS, or CP/M, even though the implementations might be quite different.

One of the advantages of MS-DOS or OS-9 over CP/M or UNIX, is that device drivers can be "mounted" rather than having to be linked into the kernal. This means that if I want to add a hard disk, SCSI graphics display, or ethernet, I only need a new driver, not a new BIOS or Kernal. If I don't need a driver any more, it doesn't eat up 20K of memory.

Ideally, if all the "componants" could be "Installed", I could change to a new VDI that had features such as "rotate figure", or a Kernal, that included Bi-directional pipes, or a driver that included "remote file systems".

Before anyone starts flaming about how you would have to give up functionality, look at "Inside Mac", "The GEM programmers guide", and the Amiga Kernal manual. Also, look at books on RT-11, CP/M, MS-DOS, UNIX, and OS-9. When you've gotten past the various different vocabulary differences, you will find that such a "generic system" would actually be better than the "proprietary" ones.

Look at how effectively UNIX hides the "disk format" compared to CP/M. All we are doing when we add graphics to such systems is extending the "stream of objects" to a wider range of objects than chars, words, lines, paragraphs, pages, files, directories, devices. On all of the popular graphics systems, a "picture" is described as a stream of objects or stream of packets of objects. In addition to the above objects, we've added lines, circles, arcs, rectangles, polygons, rounded rectangles, and fonts, many of these could actually be broken down to simpler objects, or extended into more complex ones.

Actually, there may be some real advantages to a generic operating system. As terminology becomes uniform, interchange formats, editors, filters, and applications will be easier to support, and become more general in nature. For example, I might be able to use a DBMS language like prolog, or an associative data base, to produce a graph or structure chart, use and editor similar to "MacProject" to move boxes and their connecting lines to create a more readable chart, use another editor to add additional boxes, feed the output to a compiler, and end up with an updated data base.

The hardware engineer three cubicles down, could use the same tools to feed in his wiring list, edit the schematic, come up with printed circuit board film, or gate-array programming logic, and get a bid over the phone. He might even feed the "compiler output" to the CAD/CAM film plotter on site,

and have a negative by that afternoon. Compare this to hand drawing the circuit, "mousing in" the picture, and "hand analysing" the timing characteristics.

The company president could use the same tools on his organizational chart. The systems analyst could use the same tools on his DFD's. The project planner could use the same tools on his "critical path" charts. The archetect could use the same tools on his pluming blueprints. The civil engineer could use the same tools on his "traffic maps". In fact, anyone who "connects black boxes" could use the same tools.

More importantly, they could use information they already have (compiler source, wiring lists, spreadsheet data, text, data in a DBMS,...) rather than having to manually "mouse in" the information in some abbreviated form. If you think software is an investment, think about the Gigabytes of DATA that currently has to be interpreted in the reader's mind. Don't you think that anyone would JUMP at the ability to "see" things like bibliographies, wiring lists, maps, and even source code that has been "hidden" for years?

On of the common "complaints" about UNIX is that there are not a lot of "vertical market" applications for it. In reality, there are more than anyone could imagine. The biggest problem is that they are also so "trivial" to create, that they are usually found sitting in someone's personal "bin" directory. Often, it is simply a matter of taking an existing shell script, and changing or adding a line or two to produce a DBMS as powerful as DBASE-II. One can do some really perverse things by simply examining the shell portion of tools such as lorder, cflow, tsort, lint, or diff. Many of these tools have useful "byproducts" which can be used by other tools as well.

The Mac/SmallTalk concept of One "super application" which will do "anything you might want to do" to a particular "resource" or "object" is good in theory, but then such a program, if it cannot produce by-products and accept as input, by-products, is quite limited in it's usefulness. You can't even imagine what I might want to do with your "does everything" application.

Please! He didn't say he couldn't afford it; He said he didn't WISH
to pay for the phone time.

Somehow, that makes it worse.

I should like to connect a 1040 ST to a large mainframe computer, an IBM 3084-QX running VM/CMS and MVS/JES. There are 3 ways to connect ASCII terminals to this machine, the way preferred by the operators is to use Yale ASCII. Yale ASCII is a protocol conversion system developed at Yale and supplied by IBM. Yale ASCII software runs on a IBM Series/1 mini and emulates IBM 3270 terminals for a number of ASCII terminals. The mainframe thinks the Series/1 is a 3272 local control unit with a number of 3277 terminals attached to it.

The most desirable (according to the CC) ASCII terminal is a PC or a PC clone running YTerm, another program from Yale. The second best ASCII terminal is a DEC VT100. Some TeleVideo, Data Media, Lear Siegler, and ADDS ASCII terminals are also supported.

A number of postings on this network have suggested that PC/INTERCOMM (Mark of the Unicorn, Inc.; Cambridge, MA) which emulates a VT100 terminal for the ST and a Hayes compatible modem would be a good choice.

Does anyone have an ST connected to Yale ASCII? Any other VT100 emulators which might work or maybe even a version of YTERM for the ST? Any comments about PC/INTERCOMM and Mark of the Unicorn?

If I receive any replies I will summarize and post them.

Sorry, but we don't have the resources to provide this service. Many
local user groups have picked up copies of these programs -- perhaps they can
help you.

[]
Some advantages of buying a 520ST (as opposed to the 1040):

The 520 is pretty well field tested. It's been used by a lot
of people with relatively few problems. The 1040 hasn't, so
we don't really know yet if there may be problems with the
internal drive or power supply.

The 520 is slightly more modular. If the power supply or disk
drive breaks, you can buy or borrow another one, and thus not
have much down time. If the 1040 breaks you have no option but
to have it serviced.

can i get you to forward the following note to the 16-bit digest? I get mailer errors from COMSAT@MC when I try to send it. I've just sent you a note asking to join the 16bit, so I'm worried there may be problems. Any comments? Thanks for your help.

From: Jim Moore <moore@ncsc>
Subject: ST questions
To: info-atari16@su-score

I spent this weekend with my brother-in-law who has a 520ST, and we came up with some questions I hope someone can answer:

1) Are TOS-in-ROM chips available to users?

2) Does protected software cause problems with the disk drives? He has a DSDD drive (314??) that has serious problems copying FINAL WORD (the manual

says to make backup copies). Occasionally he has to try two or three times to copy a disk that is *not* protected (eg backing up ZORK I).

3) Are there any instruction manuals for NEOCHROME available? We got a free copy from the local (Jax, FL) Games 'n Gadgets (I think it's v0.5), but no instructions.

4) Is there a Jax FL user group for 520ST's?

5) Is there a compilation of public-domain or free software for the 520ST?

Thanks for any information. Please mail directly to moore@ncsc, as I'm not on this list (yet!)

why not indeed ? i am in the process of implementing the recently
posted automatic retrival program for mod.sources and i am
considering included as much of the atari16 sources as i can get my
hands on. since when is the purpose of the net changed from the free
exchange of ideas and information ? i certainly believe that
software falls into that catagory.

Can anyone tell me how to get files thru arpanet? I can not figure out how to get files mentioned in different letters, nor can I figure how to get archived messages. Please help me. Also, I need to find out how to get uuencode. We have AT&T 3b20s, vax vms4.0, and vm/sp 4.0, what files can I get to help me out? As you can guess, I am new to the network, and I am having a tough time determining how to send for stuff....
Please help, before my brain pops!!!!

Quite a few netters have expressed interest in multi-tasking
on the ST's. Others have expressed explicit interest in OS/9.

Well, I have an announcement distributed at Comdex which answers
both of these but since I wasn't there I didn't want to rush in
(Jim O. where are you?) ahead of someone with more information.

The announcement is from

     TLM Systems Inc.
     4704 W. Jennifer, Suite 105
     Fresno, CA 93711
     (209) 276-2345
or
     67 Grandview

Pleasantville, NY 10570
(914) 747-1450

for the
OS/9 68000 Operating System for Atari ST

which is said to feature

Unix-like structure and command vocabulary
Multi-user/Multi-tasking capabilities
Shell oriented command line processing
Sequential and concurrent command execution
I/O redirection
Wildcard matching
Unix-like utility command library
Full screen editor
68000 macro assembler and development tools
Optional languages: BASIC C Pascal Fortran COBOL

selling for (I am told, it is not on the announcement) $299 without the optional languages.

In my opinion, the price will limit its appeal. For a ~$1000 system ~$300 for a second operating system is steep. Power-users with hard disks will love it but how many of them are there? The big question is, of course, how much software development will it attract?

Of course, if the same programs will run on it and on GEMDos that's another story, but I would have expected VERY BOLD presentation of that in the announcement if it were true.

I have seen the flier; that's all I know.

My 1040 internal drive gives no problems with inter-readability to
my other disk drives. However, the drive has a piece of metal that
has lately been clanging like a bell whenever the drive is started.
Also, on the subject of dimensional changes, my power supply is on the left
and does not heat up the drive. However, it does heat up the plastic of the
body of the 1040 (the cooling grill) to the extent that the plastic is
sinking into the computer. So the top of my computer is no longer flat!!!
Needless to say, I am not amused!
        Alan Kennington.

        ..
  Good peoples of the net,
now that I have two minutes together to play with my Atari, the inevitable
consequence has followed: the wretched thing has done something
incomprehensible. To wit: linking a trivial C program has resulted in the
following diagnostic: Link68 can not find ffpsub and ffpadd. But there
seems to be no difficulty with all of the fp routines required by the
Alcyon C compiler: eg fpmult, fpdiv etc. Where do I get these
ffp routines? The new version of libf from Compuserve gives the same

problem.
        Merci d'avance,
Alan Kennington.

Once again, the good is the enemy of the best. Does anybody know anything about
running GEM or Intuition or even a generic windowing system (with each window
being a virtual terminal, of course) under OS/9? That's what we really need.

Greetings,

Thumbing through the may issue of BYTE, I noticed an ad for the ever popular Avatex modem for $99.00. I remember seeing a note about a place that had them but the supply was limited. If anyone tried to get one but couldn't here is another tree to bark up.

The ad appears on page 76. It was from:

The Wholesale Outlet
DEPT. BY,
1 Interstate Avenue
Albany, NY 12205

for orders: 1-800-334-4387

I am in no way connected to this people, have no idea about them, could careless, etc, etc.

   Some poor little guy who makes $3.07/hr flipping burgers at the local
snack bar is flamed for "abusing the net", while people like andy finkel
at Commodore feel free to use *my* tax dollars to support the Amiga!
Talk about people in glass houses! Both of you guys should lighten up;
I'm sure there are people at hoptoad who spend money on things which, say,
Greg Woods at hao really doesn't give a flying fumigation about, but
do you see that nice guy with his ST (not Greg, the flamee) complaining?

(And before you point out that Commodore isn't the only company doing
this at our expense, I already know that. It's just that when a
representative (official or not) of an unmistakably for-profit company
flames some innocent citizen for "abuse", I get severely annoyed.)

The problem which many people have been having when they do the one meg upgrade was believed to be a bad MMU. Guess again. We have found that the power supply was in fact the root of the problem. By adding the extra chips, the power drain was more than could be supplied to the chips, and viola, the MMU would heat up and burn out. By increasing the rating of the choke in the power supply, you can allow greater current to pass through. We have had several units not work, but by changing the choke, all was fine. Take note, we have done 1 meg upgrades to Rev. A & B boards without problems.

I could be persuaded to send the source to my desk accessory ramdisk, of course it is meant to be linked as a desk accessory, using the development package C. If you do not have this, you might have trouble compiling the program.
The only hitch is: I am looking for somewhere to get uuencode, and archived articles/letters/files/programs.
Also, on another note, I received the installment to Tim Oren's GEM tutorial, but when I ran it through the shell on our 3b20, the checksum was not the same. Is it possible that some node along the way is expanding the tabs to spaces, since I looked at the file and found no tabs. Also, is there some way to get the macro define files needed to properly run the file thru roff, and the other files in the tutorial which were sent thru bitnet. If someone could help, I would be glad to reciprocate.

From Houston,
Michael Vederman

I can tell you that TOS in ROM Is definitely available to users--
the various dealers have them or can get them. They cost $25
and installation is extra. (List price only--your price may vary).

By the way, we received 3 copies of your message on the list.
It got through each time. SOme recipient at MIT missed
his copy, but the other 100's of people did get the message.

The hi50 hack is a very small TOS program (256 bytes) written in assembly language. It, and source, is available from the Atari BBS (don't know the numbers off-hand) plus I've seen it on several other Atari 520ST BBS's in this area (Silicon Valley). Try your local BBS. Or wait until I post it, in a week or two, when I have the time.

Franz Lanzinger

P.S. The text is quite small in 50 line mode, but it is readable.
You could even get 66 line mode, if you were really crazy.
Someday someone will do that as well, I imagine.

I should start by apologizing for the multiple postings of my previous message. I got stuck in vi (ugh) and had trouble getting back out. I thought that I had killed the messages but apparently not. I'm back in EMACS now and things are better.

Questions:

1) How do you get function keys on the 520 (in C) ?
2) Is there any timer available (again through C) that has better than 2 second resolution.
3) How do you read mouse coordinates and what translation (if any) is needed to find screen coordinates.

My thanks for any help that makes it my way.

Neal McWhorter

I remember reading somewhere that you can avoid the subdirectory problem in the DRI linker by placing the file names to be linked in a command file. This file can be taken by the linker by saying 'LINK68 output-file-name = [COM[some-file-name]], other-files'. The '[COM[some-file-name]]' takes more commands from the file inside the inner brackets (commonly uses a .INP extension).

The problem comes from the linker thinking backslashes as comment characters when on the command line. I actually haven't tried the command file idea, so it may not work...let me know what happens. In any case, the fix is probably reasonably trivial, and I am not sure why it hasn't been fixed. My guess would be that the ST is not at the top of DRI's "list of importance projects" right now.

Hello, world!
Has anybody run into the following problem with malloc() under DRI C?
The program

```
main()
{
     int  i;
     extern char *malloc();

     appl_init();  /* optional */
     for (i=1; i<16; i++)
          printf("malloc() returns %lx\n", malloc(i));
}
```

produces output whose high word is always 0 or 0xffff- i.e. is getting
sign-extended somewhere- and whose low word looks reasonable- i.e. increments
by 16 with each call. Worse yet, on the eigth or so call, malloc() starts
returning NULL, even though gobs and gobs of memory are available, and
the DOS call Malloc() has no trouble allocating 1K before the loop...
WHAT THE HELL IS GOING ON? Maybe I should just use the DOS malloc, eh?
Thanks in advance.

I am currently interested in writing a desk accessory in TDI Modula-2 or
OSS Personal Pascal (which should be in the mail soon).

If someone has written a desk accessory in either of these languages,
perhaps they could send me a copy.

I tried just renaming the excutable file of one of my Modula-2 programs
to whatever.acc, and the OS doesn't manage to boot.

Are there any limitations associated with desk accessories? Are they
restricted in the memory they can use?

Thanks in advance,

Eric Bergman-Terrell (CSNET Address terrell@ohio-state)

> exchange of ideas and information ? i certainly believe that
> software falls into that catagory.

It seems to me that if I pay to transmit your free exchange of
ideas is ceases to be free.

You can send whatever you want at your expense, but when you ask
me to pay for it (even implicity) you give me the right
to interfer with it.

I remove an average of 2 full source copies of rogue or hack
from the mail queues on seismo each week.

It takes about $45 worth of phone time to transfer that
free exchange of information. Federal Express and a mag tape would

only be about $40, yet how many people ever think about it. It cost
them nothing to mail it electronically (except for the non-North Americans).

I really wish the US had some sort of recharging scheme like they
do in Europe.

Is there really an extremely high correlation between the belief in the
obligation of free exchange and 1/(number of users your computer supports)
or am I overly sensitive.

The problem with the linker not being able to find the routines
ffpadd and ffpsub is now solved. And this is what I found:
The linker goes through the library finding undefined symbols,
including only the object code necessary for the undefined symbols
not yet found during the search. Now my program was so simple that
it did not need fpadd or fpsub, which therefore do not need to call
ffpadd and ffpsub. But fplog calls ffplog, which comes AFTER ffpsub
and ffpadd, and therefore calls them unsuccessfully. The order of the
relevant files is:
fpadd.o
fplog.o
fpsub.o
ffpadd.o
ffplog.o
(I think ffpadd.o contains the entry point ffpsub also.)
Thus the problem seems to be simply that the library has the object files
in the wrong order. I tested this conjecture by including a floating
point add and subtract in my program. And ....It worked perfectly!!!
Following is a list of contents of the new libf downloaded from Compuserve:

Rick,

I do not hear you complaining about receiving (and paying for) files that
happen to interest you. Perhaps if all of us restricted our postings to
subjects in your interest area, we could all pitch in and solve your little
problem.

Just write down a list of the things that you personally would like to
see posted to the net, and all of us will promise not to post anything else!

Eric Bergman-Terrell (CSNET Address terrell@ohio-state)

Yes. I'm writting a desk accessory in OSS Pascal. The folks who wrote OSS Pascal posted a whole series of helpful hints to CompuServe about a month and a half ago. These included instructions on how the make a desk accessory, set up the serial port, make VDI and AES(?) calls, etc, etc.

I think all the stuff is in DL 3 in the 16 bit Atari SIG...

Hi there.

I'm having some difficulty deciding which ST to purchase. I thought that the 1040 was the machine to buy, but I would prefer to have the power supply and drive external to the system. So I thought, I might as well get a 520 with a double sided drive. But I've been told that upgrading the 520 isn't so easy due to the lack of space inside the case.

Can anyone shed any more light on this subject? I'm particularly interested in the ability to expand the system, especially along the lines of extra RAM, and the graphics co-processor (when it becomes available).

Any help would be appreciated.

>been on net.micro.atari16). Some of the questions are:
>1. Is there any copyright infringement? I believe there is none, but
>   the developer thought Apple might so claim.

This depends on whether Apple is depending solely on copyright protection
or a liscence agreement. If copyright is the only restriction, then
Apple dealers, who have purchased the ROMs legally, may resell them
to anyone who wants to buy them legally. However the upgrade policy
for the Mac to Mac+ upgrade stipulates $$ PLUS the ROM. Apple already
gives service centers ROMs with credit/charge policies. It is quite
possible that Apple Dealers would be perfectly willing and able to
sell you an Apple ROM for $1000 or more.

>2. Can Apple suddenly claim the roms as proprietary? The roms are
>   evidently availble (officially) for somthing like US$195.

They don't have to. They are already covered by well documented copyright
notices. They have probably also registered the copyright.

>3. If Apple tries to restrict this product wouldn't they expose
>   themselves to restraint of trade claims?

This would be a problem ONLY if the "bundling" were a restraint of trade
in that it was impossible to get the same functionality, product, software,
... for the other machine, and that the purpose was to maintian artificially
high prices. Atari's low price may enable customers who buy both Apples
and STs to file such complaints.

Some important cases are the NOVA case, the IBM "bundling" case, and the
Apple vs. Fanklin case. In the latter case, Franklin attempted to prove
"restraint of trade" via the ROMs, and lost.

Personally, I would hope that they could come up with an object code
translator, as Landon did for the Amiga, or maybe Atari will come up
with translaters to go Atari-> Mac, and Atari -> Amiga. Another possibility
is that a third party such as DRI, MicroWare, Metacomco or ??? could come up
with operating systems which would provide the best functionality of all these
machines and still be tranparent to application software. Possible candidates
include Concurrent GEMDOS (is it coming?), OS-9 68K, Tripos, GNU with VDI,
Windows, UNIX, or ???. At this point, it looks like OS-9 will be the first
contender.

There is too big a potential market for "compatibility" between these machines,
and too many new peripherals (CD-ROMs, WORMs,...) which can't be released
in a timely fashion if four separate interfaces and systems must be supported.

The "componant computer system", like the "componant stereo system" will
be an important factor in the future. Manufacturers may produce "compact"
versions, but users will still want to plug in additional "black boxes"
that shouldn't need to know what computer they are connected to. This
also includes software.

Hopefully, by the end of the year, this will have all sorted itself out,
and we will be able to "Mix and Match" componants from a variety of
manufacturers. Mac+ is the first to "Throw the gauntlet" with built-in
SCSI. IBM dealers and users are already beginning to follow suit.

Interestingly enough, Atari, with their "lowball price" and "high power"
stand to gain the most from such a situation.

You need the later version of the Hard Disk driver program! It has been
posted to the Atari Developers SIG on CompuServe. Check with the developer
support person at your closest Atari office if you're not on CompuServe.

True. There are some limitations with portable technology.
After having designed a portable for Commodore, here are some
of my thoughts...

1. Motor (in disk drives) and Batteries are mutually exclusive.
   Solid state mass storage is the only way. The entire Commodore
   LCD computer ran on less than 100mA from 4 AA cells. The lowest
   power disk drives today are FIVE times this hungry, just for the
   disk! Here we have the classic case of the tale wagging the dog.
   Hard disks...forget it.

2. LCD displays are still expensive. An 80x25 line display adds about
   $300 to the list price of a computer. It just can't compare to
   a $99 monochrome monitor. Color LCD look terrible. There have
   been recent advances in LCD technology called "SuperTwist" which
   have a much better viewing angle, and a yellow/green background
   with black letters. But the electronics to drive this display
   is still VERY costly. (16 plus 100 pin flat packs)!

3. CMOS memory is always one generation behind NMOS memory (DRAMS).
   How's 64 - 28 pins packages the size of an EPROM hit you for 512K?
   Customers of course don't understand why you can buy a Tandy
   1000 PC clone with monitor for $999, but still you must pay TWICE
   this for a portable PC clone. (Toshiba's got a new one out)

4. Mice. All these new computers have mice. What in the $%&# do
   you do with a mouse on a portable computer? "Excuse me, can
   I borrow your leg to roll my mouse on?" Nice pick up line, eh?
   Or, "Now which pocket did I put that mouse in...hummm...".

5. Does anyone make a CMOS 68000?

Well, there have been alot of manufacturers looking for the magic
formula for portable computers, but NO ONE has found it yet. I am
afraid we must wait for technology.

Hello folks,

I have a TEO PX-80 printer which is a lot like the EPSON MX-80 in terms of escape sequences it recognises. Anyway, during the Christmas holidays, I generated a printer driver that does *all* the First Word characters (the greek alphabet and math stuff and all). It does all the standard characters by simply printing them out, and the same goes for bold and underline and other escape sequences which my printer understands, but all the other "funny" characters are done by bit-image printing. It should be quite easy to modify the file for an Epson compatible printer, but if you have a completely different printer, this is the way to make designing the font easy.

The technique I used required Degas (yes!), the manual for the BASIC and a convenient Unix system (optional). First, open the BASIC manual to page E-1, pages E-1 and E-2 show what the 8x8 font looks like on a grid. Next, start up Degas(TM) and chose "Define brush" option. This will present you with an 8x8 grid (!), simply use the mouse to click on and turn on and off the fat-pixels until you get the "up-arrow" (
(say).

My apologies if these seemingly simple questions have already been
addressed here on the net.

1) How do you determine if a function key has been hit on the 520?
    I'm interested in doing this through C and I have both the DRI
    and the Lattice Compilers available. I've tried most everything
    I can think of following up on the hints that the Hitchhiker's
    Guide offers about similiarities between the 520's function keys
    and the IBM PC's but no luck.

2) Is there a way of accessing the system clock to do timing other
    than using the 2 second resolution accesses that are documented.
    Again through C.

My thanks in advance for any help.

Can anybody tell me how to program the AY-*-* sound chip built
in the ST? It looks rather difficult to me to do this via the
Giaccess() call every time, cause it's hard to tell which 16
bit number plays a middle C.
Maybe someone could explain how the xbios-call do_sound() works.
I'm writing on a music application which plays sheet music, but
should also be able to use the simple synthesizer possibilities
of the sound chip, such as attack, hold, continue, vibrato.

Anyone knows about the AMY sound chip that is being developed
(when it's coming out, prize, etc.)? I became very curious
when I heard about it's the great features, which can concur
with professional synthesizers.

To those who may be curious:

I finally received my copy of MetaCompco PASCAL for the
Atari ST series. It was written by the folks who brought us Lattice C.
I purchased it through Antic Publishing, and, after a series of wierd
experiences with them, it finally arrived in the mail.

Opinion? I like it quite a bit. It is a full ANSI PASCAL implementation
and then some. It does *not* seem to have the limitations that OSS Personal

PASCAL is said to have. Also, it has full access to the VDI and AES libraries. (As a matter of fact, the calls seem to be directly taken from the Lattice C VDI and AES calls. That's fine with me since I can use the ABACUS books to describe the calls in detail.)

It comes with the MetaCompco full screen editor, which - although it is no EMACS or VI - is quite useful. It also comes with the MetaCompco linker, which is a full function linker that allows you to do all sorts of magical things.

The PASCAL compiler also has a switch to allow you to create an object code that can be linked to object codes created with the C that comes with the Developer's kit.

All in all, it is a very nice package that allows you to do some impressive things. And, of course, the price is right at $79.00.

Tee hee. Talk to Jason ("Born To Code") Loveman, the original author of
GEMDOS (TOS). The "number of subdirectories" limitation is the result
of one of his brilliant ideas on how to make a "better" OS.

Jason no longer works at DRI; he started his own company, Awesome [sic]
Technology, just before the ax was about to fall on him here.

Hi there.
  This is my first message out to the mailing list. And assuming
this actually goes through (I'm a pioneer at this over here...
no one else seems to know what to do), I have a question which
I wonder if someone would kindly answer either through the
mailing list, or with a private message.

  Namely, could someone please explain to me the differences
between the Atari 520ST and the 520+ ?? I'm writing a small
article and any information would be greatly appreciated.

David Pullara

Finally some MIDI software for my ST.

I finally bought a MIDI sequencer for my ST. I shopped around
and decided for 'Midirec-I'. Other contenders were 'Soundwave'
and something else whose name I do not remember.

The interface is simple and menu driven.

The basic features are:

```
     record up to 30,000 notes (less with key-velocity/pressure info)
     playback (with variable speed control)
        Save song to file
     Load song from file
     Built in metronome (really nifty, with beats/measure, tempo control and
             other nice features)
     +  others
```

MInimum requirements are a 520 ST with a disk drive, either monochrome
or color monitor (I have both ;-)).

The system is configured for future expansions such as patch librarians
and programmable sound effects.

I tested it on a Yamaha DX-7 and a Casio CZ-100 and it works without
any problems.

The program is really fast, written in forth, and they say you can
buy the sources to add your own features.

I discovered no bugs, and the price/performance was great.

After I decided to buy Midirec I went to the local music store
and they were all out, so I mailed 29.95 to the MIcroB (weird name)
people and got the program in 3-days (almost immediate gratification).

Microb's address is:

MicroB Software
1016 E. El Camino Real, Suite 392
Sunnyvale, CA. 94087

As usual

I am in no way related, even remotely to MIcroB software, and
all the usual stuff, just a happy customer getting the right
program for the right price.

jfb

P.s. Also, this is all only my opinion, and not that of my Employer (or
my mother).

Sorry folks. Retrofitting a modulator is not in the cards. The dealer must
have been misinformed -- but not by Atari.

The ROMs have been in stock again for a couple of weeks. They did not land
in any hostile third world countries. Dealers can order them from us. If
your dealer can't get them, you can order them from us by sending $25 and a
letter which states that you understand that Atari is not responsible for any
damages to your 520ST caused by improper installation by unauthorized
parties.

This is actually the grand Microsoft tradition. MS-DOS has an almost
identical method for catching ^C, using INT 23H. Jason ("Born to Code")
Loveman put it into GEMDOS (TOS) as part of his plan to be as similar to
MS-DOS as possible. Read IBM's DOS Tech. Ref. if you want deja vu.

Is the hard disk going to be a straight plug like promised or will we need
to supply the cables and plugs?

Neil @Atari Customer Relations
1196 Borregas Ave.
Sunnyvale, CA 94086:

Is a schematic and/or service manual for an Atari 600xl available from Atari Customer Relations? If so, at what cost? And where do I write or call to get one? Is the above address correct?
Any help in this area would be appreciated.

Thanks in advance,
John Steele

Summary: May 9 to May 23 w/Guest Experts

I'm most pleased to announce a Special Conference on OS-9 68K

from May 9 to May 23 on the Byte Information Exchange. Our guest
experts shall be:

     Peter Dibble, columnist and author on OS-9, (whom we all know :-)
     Peter Gallanis of MicroTRENDS who among other things will be
     marketting the Atari ST OS-9 port.
     Peter Beaven of TLM Systems who did the port.
     Brian Lantz, the President of the OS-9 Users' Group
     Frank Hogg, FHL who sell the QT series of OS-9 68K computers.
     Bob Moore of Microware, the creators of OS-9.

ing to have a lively series
of discussions.

                                    Cheers! -- Jim O.

    I am having the following problem with a program I am writing using the
  Personal Pascal language. I keep getting the following runtime error dialog
  message:

         BUS ERROR ACCESSING $FFDC12DA
         ERROR IN *unknown*
         AT PC $00022638

  followed by the dialog message:

NOT YET IMPLEMENTED
ABORT?

After clicking "Yes" to the abort msg, the menu bar no longer responds, and I must reset to continue. Can anyone shed light on what is going on here, and how can I decipher the error messages of the above type?

Thanks,
Gary Letourneau

The recent letter from neil @ atari confuses me somewhat. He says
that 1040's will not be refit [Dted with rf modulators and that it was
not atari's intent to confound the dealer who reported this. Does
neil @ atari meen [D[D[Dan that 1040's will not support rf output ever? If
this is the case then someone should get in touch with the advertising
people who composed that beautiful two page add in the June issue of Byte
which says that the 1040 can be connected directly to a colour TV. So
what is the scoop guys? Will the 1040 come with an rf modulator or not?

I have just bought a copy of a magazine from the U.K. called
Personal Computer World with an article on the 1040ST. This
article is very positive on the ST family with only one 'sour' note:

" After conversations with users and dealers of the 502 ST, its
appears that there is some doubt as to the reliability of the
system. One dealer reported 18 of his 30 Systems being returned
to Atari and, of the users I know, everyone has experienced at
least one hardware fault. The system in the office of Personal
Computer World has gone through one mouse and one monitor in
about four months, and the 1040's disk drive is rather
temperamental."

I would appreciate comments on the above statement as I have

ordered my ST1040 now and I am now considering cancelling this
order if the above is TRUE.

Thanks for any information

Peter Verbruggen

Rank Xerox ,Venray

p.s. the 1040ST cost $1543 overhere !!!

I believe you can reduce the number of disk swaps during copy to 3 if you copy file F from B to A instead of from A to B.

Another hint: When copying disk A to disk B by dragging the disk A icon to the Disk B icon, dialog boxes which request that you swap disks appear before the copy operation commences. Swapping disks at this point is unnecessary. Simply click on ok two times and proceed with the copy. Similarly, upon termination of the copy process two dialog boxes request two disk swaps. You can ignore these also. If you haven't been doing this already you will appreciate the time savings.

Has anyone else with Lattice C (3.03) for the ST tried to run LC1.TTP and/or LC2.TTP from within a shell program or a make program? I downloaded a "tiny shell" accessory from a BBS and a PD make program from net.sources and neither of them seem to be able to start LC1.TTP correctly. LC1.TTP comes up and causes an error something like this:

"Your computer doesn't have enough memory to run this application"

This same error occurs each time I try to run it, even after a reboot. Now I know that sizeof (tiny_shell.acc || make.ttp) + sizeof (LC1.TTP) cannot fill up all 1Meg in my 1040ST! (Or can it?) Running LC1.TTP from the GEM desktop with the same parameters works fine. Tiny shell works fine for other programs, including Lattice's editor (ED.TTP).

Am I incorrect in assuming that these programs CAN be started from a shell or a make program? After all, LC.TTP runs them! If anyone knows how this can be done, please let me know.

Robert Cagle.

Of course one can always buy a TV modulator and feed it with the composite
output that someone just mentioned in a previous note (or was that only on the
520ST?).

If no composite output is available, it can be cooked up from RGB with an
NTSC modulator chip as noted in an earlier message from me.

Is there a C++ compiler for the ST yet? All news, rumours and reviews are appreciated.

Forgive me if this has been discussed before. Does anyone have Megamax C? If so, what are it's pluses and minuses? Documentation? Does it come with additional utilities (make,editor,command-shell,etc.)?

Thanks in advance

    A few people who have amiga's have gotten this modem.
(theres a special deal $200 modem,software, and cable). They seem to be
satisified with it. I may get one when I get my amiga.

This evening I wrote a little program to set the system time and date for my
520ST. When I ran the program, it did actually change the time and date as
expected.

Since I wanted this program to be run at boot time, I placed it in a folder
named AUTO. When I booted up, my program was run, but the time and date
were unchanged by my program.

I think what happened is this: my program set the date and time perfectly.
After the program finished, the date and time were given their default
(and strange) values by the system.

THE PUNCH LINE:

Is there a way to get a program in the AUTO folder to run after all system initialization is completed?

Thanks in advance,

Eric Bergman-Terrell

When I use AtariWriter to set either subscripting or superscripting, I can never get out of sub or superscript mode. How does one return to normal printing after sub or superscripting is set?

I really have studied the printer's manual!

Thanks in advance,

Having tried the 520ST's built-in VT52 emulator with a Vax, I
find that the function and cursor keys send only nulls, and the
numeric keypad keys send only 0, 1, 2, 3, etc. This makes it
virtually unusable with an editor driven by escape sequences and
the question therefore is: can I program these keys to send
characters, or sequences of characters, of my choice? I don't
have any compilers, etc., only the software that comes with the
machine.

Any advice would be most welcome.

Summary: mine doesn't

I've had my 1040 for about 3 weeks now and I have yet to notice *any*
obnoxious noises. I recall that people were complaining about the disk
drive squealing; I think this would indicate a serious problem and that
you should take it back to the dealer for repair and/or replacement. I can
believe that the ST has a bit of a quality control problem, since my machine
came with a bad monitor cable and a bad connection from one of the mouse
buttons -- fortunately both problems were easily fixed.

I'm not at all convinced that OS-9 has much chance here. And, I don't think
it has anything to do with how good of an OS it is (unfortunately). I would
expect that GEM may have the best chance. Why? You can get off the
shelf applications for GEM of the sort that most people are interested in.
Languages are not applications. Spreadsheets, Word processors, painting
packages, DBMS programs, games, THOSE are applications. People want to buy
PeeCee DOS emulators for their machine, NOT OS-9, and certainly NOT because
PeeCee DOS is a better OS. GEM is not owned by one of the hardware
manufacturers, who would probably want to keep you locked in to their
hardware and not let their OS run on other machines. This is what will rule
the MAC OS out. TRIPOS would only have a chance if Amiga would consider
selling Intuition (their graphics/windowing software) to go with TRIPOS.
This would actually be in Amiga's best interest, TRIPOS and INTUITION running
on a ST would sell a lot of Amigas, both by expanding the attractiveness to
developers of developing Amiga compatible packages, and by magnifying the
performance and feature differences of Amigas vs STs. Otherwise, TRIPOS
has the same problems as OS-9. GNU might have a chance, because it's free.
There is no way I am going to BUY an OS for my machine even if it is a great
OS, if there are no (or almost no) applications that run under it. If it's
a FREE OS, (public domain or similar) THEN I might be inspired to run it on
my machine. If Atari, Amiga, Apple or some Alternate manufacturer produces
a machine that comes with OS-9 plain vanilla, and developers decide to get
behind it, then OS-9 has a chance. Until then, OS-9 is at the level of the
8-bit CP/M systems, because there will be no applications that will use any
graphics, windows, or other neat stuff that you need to sell applications
these days. I don't need OS-9 to run 'C', assemblers, Modula, Pascal, Lisp,
Basic, Forth, etc. on my Amiga, or to be able to print stuff while I'm
editing or compiling now do I?

Here is a short utility for the Atari ST that sets the time and date
on power up. It's especially useful to MAKE users. The MAKEFILE
follows the source code.

```
/* SETCLOCK.C

   Routine to set the clock on startup (Atari ST).

        Copyright 1986, Brian Bray

        This software may be freely copied and given away for
   non-commercial use, but sale is prohibited.
   Upgrades and comments should be sent to:

        Brian Bray
        #306, 10135 - Saskatchewan Drive
        Edmonton, Alberta
        Canada  T6E 4Y9

   or on UNIX.

        bray@alberta.UUCP

Usage:

   This program is intended to be placed in the "auto" folder of a
boot disk.  On power up, it asks for the time and date and sets the
clock.  It will not reset the date during a reboot,
only on power up. (Another mystery!).

   86/04/30     Brian Bray      Release
   86/04/25     Brian Bray      Called BIOS getline.
   86/04/24     Brian Bray      Removed scanf to make smaller
   86/04/22     Brian Bray      First version
```

I forgot to mention in my previous article that the SETCLOCK
program doesn't work with TOS in RAM (Agatha rules!).

Whatever you do is a hack to fix the 68000 clr instruction. But for
those that do not have the asm{} feature you might try:

```
{
     long qwe;
     qwe = 0;
     *diskctrl_l = qwe;
}
```

This means that Neochrome, which came with my 1040, is useless and always will be. It means that my user's manual is inaccurate, and that when it tells me about how to connect up the TV set it's talking fantasy.

I do want a color output short of getting the color monitor. I have a TV set with a video (composite) input jack. In my previous posting I said I'd checked pin 2 of the monitor connector and it was dead: in fact this wasn't true, a scope shows an output there, but it wouldn't drive the TV. What exactly is this? Someone else was saying that it is indeed composite video; if I haven't got what the literature promises, then what do I have?

An interview with Jack Tramiel by David Bright appears in the 28 Apr 86 (or do you like 860428 so you can sort it?) issue of ComputerWorld.

Attributed to Tramiel are assertions that 200,000 ST systems have been sold so far, about 70% outside the USA, and that Atari has gone from losing $10**7 / month to a profit of $9*10**6 / quarter since he took over (actually in the black before the STs started shipping.)

Some market research skepticism was expressed over the total sales figure but if we accept it that's about $200M market value.

Compare this to the DEC (second largest computer company) MicroVax II also introduced last May. Its 1985 sales were reported in the same issue as 12,000 units. At a system price around $25,000 that's a market value around $300M and it's considered a spectacular success.

Tells you something about the motivation of people who are putting down the ST, doesn't it?

Although there has been a prototype of an ST add-on to run IBM-PC
programs, Tramiel is cited as indicating that before that would be
available Atari would have an IBM-PC card to run ST programs.

Sounds like you shouldn't hold your breath.

Larry Samuels of Atari indicated more than 300 software packages
are already available for the ST systems.

I am at point to buy an Stfamily computer system. Is there a way (eg by reading
one or another memory location or whatever) to find out what the revision level
and the TOS software version are? Could anybody propose a small basic program
to get these figures, that I can use while testing one in a store?

The next question of course is which revision level and which TOS version are
the most recent ones? Please specify your system type as well (ST520, ST520+,
or ST1040). (BTW, Is the 520ST+ (520model with 1Meg memory) only being sold in
Europe?)

There is a public-domain date and time program that I am using that works.
I'm not sure what the difference is but it is possible to set the date
and time 'permanently' in spite of when programs in AUTO run.

What about access times for the St Hard Drive? The transfer speed is fine, but what about track to track speeds and such? In any case, is there a firm release date yet? I want one.

I believe that one of these requests has come up before, but I
am unable to find it in my archives...so please be patient with me:

I am looking for the name of a company (or individual) that will digitize
images for me in Atari ST NEOchrome or DEGAS format. (Some idea of their
cost would be appreciated.)

My second request is: does anyone out there have a copy of the NEOchrome
or DEGAS file format?

Please e-mail your responses to me...if anyone else would like the same
information: just ask.

Thanks in advance.

I really need to get a RAM disk program. Are there any on the market

that are good? If you have such a program, please send a review to me
or to this net. I am interested in how big a RAM disk you can set up,
whether or not the program is copy-protected, how much RAM is left over
when the RAM program is running, etc.

Also, there was a RAM disk program sent to the net a few weeks ago.
WOULD SOMEONE BE SOOOOO KIND AS TO SEND ME ALL THE ASSOCIATED FILES?

Thanks in advance,

*** REPLACE THIS LINE WITH YOUR Answer ***

I'm trying to write a desk accessory that can enable/disable itself
on the desktop menu. If possible, I'd even like to change the text
on the menu. I've tried to use multiple MENU_REGISTER calls but
apparently only the first is used. In order to use the other MENU_
calls, I need the address of the desktop's menu object. I've poored
through the developer's documentation but can't seem to find anything
relevant. Any help/pointers would be appreciated.

My application is a realtime clock cartridge for the ST. It'll
also have EPROMs for about 64K of stuff. Any suggestions (non-obscene)
for what I might put there ?

Subject: Standard OS for 68000-based PC's

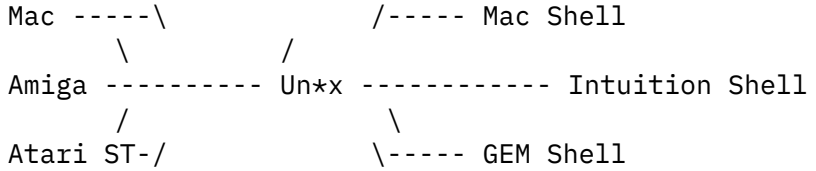
Dave,

Your idea of one supported OS for the various 68000 machines is not unique. I think the main reason that various workstation vendors (Sun, Silicon Graphics, Masscomp, etc.) went with Unix rather than develop their own operating systems was that they bought into a big software base and saved themselves countless amounts of money developing something that just wouldn't cooperate with anything else. Why Apple, Atari, and Commodore didn't see this light I am not sure. Since they now each have their own (proprietary) operating system, it's unlikely that they will change.

What if you could pick and choose between three pieces of hardware, one unifying operating system (some dialect of Unix jumps to mind), and three (or more!) graphic shells?



It sure would be nice! Perhaps we could all start off with a decent base of

software tools: compilers, SCCS, make, {n,t}roff, etc. Oh well, someday
maybe someone will market a PC with that kind of foresight...

==========
In the Toronto area, we get mixed reports on the reliability
of the double sided floppy drive (the one in the 1040). One specific
complaint is that a disk written on one drive may well not be
readable on another drive.
A suggestion was made thatthe heat from the internal power supply
on the 1040 might be causing dimensional changes in the drives.
Any comments from netland?

>Does anyone have any comforting words for me?

Well, if you do get stuck with an SF354, you can easily upgrade it by swapping
the floppy disk drive unit with an EPSON SMD-180 double sided unit. This makes
a reasonable alternative to trying to swap or otherwise get rid of the single-
sided drive, especially if you got stuck with a 'package deal'.

Obvoiously, this would void the warranty on the drive, and you also might
need to make a group purchase on the EPSON drives to get a good price, but
those single-sided drives are pretty worthless....

There are 2 different system clocks in the system. You set the wrong one.
I have a PD program that lives in my AUTO folder and sets the clock. It
works perfectly.

GEMDOS $2B is SETDATE
       $2D is SETTIME

XBIOS 22 is settime.

Both these calls are equivalent, and to the WRONG clock.

The correct call is XBIOS call 25, ikbdws, which sends a command to the
intelligent keyboard. You must send ikbd command $1B, set clock time.
This is the clock that determines the system time at bootup.

Summary: Why should we care? Expandability!!!

I seem to be having some trouble getting this information, and
need to know SOON.

Several magazines have pointed out that the Atari OS will be
using X.3t9 (SCSI) protocol between their drives an the ST.

What I'd like to find out is:
Will REAL SCSI be supported, or will the DMA be Yet Another Proprietary
Interface? Since a few of you have ad a chance to see the new
ST hard drive, I was hoping I could get some more info.

One of the reasons I'd like to find out is that there are some real
good deals on surplus ST-506 drives, and a real cheap (under $150)
SCSI to ST-506 adapter cards/chips coming out.

I know Atari has been holding up the hard drive until the hard drives
could be made real cheap, but what is the hold-up on the interface?

If Atari comes out with nice, low cost SCSI drives, could they
be used on a MacPlus?

If Atari is not going SCSI :-(, will they be coming out with a
good backup system in the near future? Feeding 20+ floppies
for an hour or two, just doesn't sound like fun.

Atari has avoided most of the mistakes that were made with the
800. The printer, serial, and MIDI interfaces are nice and
standardized. The floppy and video interfaces are a little
weird, but not to the point where it is a major drawback.
Let's hope the "DMA" interface is as well thought out.

For the folks who haven't seen it yet, there's a real nice
write-up on SCSI in the May issue of Byte. Ciarcia(sp?) is adding
one to his SB-180.

Lines: 40

In BYTE (May, '86) a bulletin board sponsored by ATARI was announced.
There are four different lines:

1-408-745-5308
          5970
          2642
          4758

The BBS has 9 different special interest groups (SIGS):

1. General
2. XE
3. User Groups
4. Dealers
5. Service Centers
6. Developers
7. ST Art
8. ST Computer
9. SYSOPS

Set your modem to no parity, 1 stop bit. I managed to log in with my
1200 baud modem. I believe 300 baud is supported also. When I stumbled
around the BBS it looked like there was a lot of interesting software to
download. Files could be downloaded in ascii, xmodem, and some other
format. One can log onto the service for a period of twenty minutes.

I tried to download some programs, without success. I could download
text files with no problem, but programs got screwed up somehow.

I have the PC Intercom program (an early version). This program allows one
to download files in ascii, raw, modem7 (whatever that is), and
PC Intercom modes. I tried ascii and raw without success.

Would someone who has been successful downloading programs please let

me know how it is done? I'm completely stumped.

Thanks in advance,

Eric Bergman-Terrell (CSNET Address terrell@ohio-state)

I've had my 520ST for about 5 months now without a bit of trouble. I've done the upgrade (complete with resistors), and installed ROMS's without incident. I leave everything but the monitor on 24 hours a day. I'm not sure if that's supposed to be good or bad for it. Anyone know? The only precautions I've taken with mine are to use a filtered-to-death ISOBAR power supply, and to crate up the beast in it's original boxes if I take it anywhere. All in all, I'm quite impressed by the reliability.

X.PART X VDI Graphics: Text Output
X.PP
XThis  issue of ST PRO GEM concludes the two column series  on
XVDI  with a look at simple VDI  text output,  and ways to optimize
Xits  speed.   There is also a Feedback section.   You may find the
Xassociated  download  file under the name GMCL10.C in DL3  of  the
```

XATARI16 SIG (PCS-58).
X.PP
XTo keep the size of this first discussion of text within
Xreason, I am going to restrict it to use of the mono-spaced system
Xfont in its default size and orientation. Discussion of
Xalternate and proportionally spaced fonts, baseline rotation, and
Xcharacter scaling will become a later article in this series.
X.SH DEFINITIONS
XThis article makes use of some terminology
Xwhich may be unfamiliar if you have not used digital typefaces. A
Xmono-spaced font is one in which each character occupies an
Xidentically wide space on the screen. A proportional font has
Xcharacters which occupy different widths. For instance, an 'l'
Xwould probably be narrower than a 'w'.
X.PP
XText may be "justified" right, left, or center. This means
Xthat the right character, left character, or center position of
Xthe text string is constrained to a given location. In common
Xusage, a page of text is "ragged right" if its lines are left
Xjustified only. The text page is "fully justified", "justified"
Xor (ambiguously) "right justified" if BOTH the left and right
Xcharacters are contrained to fixed columns. Full justification is
Xproduced by inserting extra blank characters in the case of a
Xmono-spaced font, or by adding extra pixel columns in the case of
Xproportional output.
X.PP
XA text character (in a monospaced font) is written inside a
Xstandard sized cell or box. Vertically, the cell extends from the
X"top line" down to the "bottom line". If there are one or more
Xblank lines at the top or bottom, they are called "leading" and
Xare used to separate lines of text. The characters themselves
Xalways fall between the "ascent line", which is the highest line
Xreached by characters such as 'd' and 'l', and the "descent line",
Xwhich is the lowest line in characters like 'q' and 'g'. Other
Xlocations of interest are the "half line", which is the top of
Xcharacters like 'a' or 'n', and the "base line", which is the
Xbottom of characters which do not have descenders.
X.PP
XBefore plunging into the Attribute Functions for text, you
Xshould note that the writing mode (vswr_mode) and clipping
Xrectangle (vs_clip) attributes discussed in the last column (#9)
Xalso pertain to text. Since much of the discussion of text
Xoptimization will center on these attributes, you may want to
Xreview them.
X.SH TEXT ATTRIBUTES
XThe writing color for graphics text is set
Xwith the command:
X.FB vst_color()
X   vst_color(vdi_handle, color);
X.FE
XVdi_handle is always the handle returned from graf_handle() at
Xapplication startup. Color is a word value between 0 and 15 which
Xdesignates the output color index. As discussed in previous

Xcolumns, the actual color which appears is dependent on the Xcurrent palette settings. In applications such as word and Xoutline processors it is important that characters and their Xbackground provide good contrast to avoid eyestrain. In these Xsituations, you may want to use the setPalette and/or setColor XXBIOS functions to force the palette to a known state before Xstarting the application.
X.PP
XYou can choose a variety of special output effects for your Xtext with the call:
X.FB vst_effects()
Xvst_effects(vdi_handle, effects);
X.FE
XEffects is a single flag word, with the bits having the following Xsignificance:
X.BO
X0 - Thicken
X.EO
X.BO
X1 - Lighten
X.EO
X.BO
X2 - Skew
X.EO
X.BO
X3 - Underline
X.EO
X.BO
X4 - Outline
X.EO
X.BO
X5 - Shadow
X.EO
X.PP
XIn each case, turning the bit on selects the effect. Otherwise, Xthe effect is off. Any number of multiple effects may be Xselected, but the result may not always be pleasing or legible.
X.PP
XThe "thicken" effect widens the character strokes by one Xpixel, resulting in the appearance of boldface type. The X"lighten" effect superimposes a half-tone dither on the character. XThis mode is useful for indicating non-selectable text items, but Xis not legible enough for other purposes.
X.PP
XThe skew effect shifts the rows of the character the right, Xwith the greatest displacement at the top. This results in the Xappearance of italic text. You should be aware that the VDI does Xnot compensate for this effect. This means that a skewed italic Xcharacter which is immediately followed by a normal blank will be Xoverstruck, and part of the top of the character will disappear. XLikewise, a skewed character written to the left of an existing Xnormal character will overstrike part of it. There is a related Xbug in the VDI clipping logic which may cause some parts of a

Xskewed character not to be redrawn if they fall at the edge of a
Xclipping rectangle, even though they should fall within the
Xregion.
X.PP
XThe outline effect produces output which is a one pixel
X"halo" around the normal character. The shadow effect attempts to
Xcreate a "drop shadow" to the side of the character. These
Xeffects should be used very sparingly with default sized fonts.
XThey often result in illegible output.
X.PP
XWhen graphics text is written, a screen coordinate must be
Xspecified for the output. The relationship of the text to the
Xscreen point is determined by the call:
X.FB bst_alignment()
X   vst_alignment(vdi_handle, hin, vin, &hout, &vout);
X.FE
XHin and vin are each words, with values specifying the desired
Xhorizontal and vertical alignment, respectively. Hout and vout
Xreceive the actual values set by the VDI. If they differ from the
Xrequested values, an error has occurred.
X.PP
XHin may be set to zero for left justification, one for center
Xjustification, or two for right justification. The coordinate
Xgiven when text is written becomes the "anchor point" as described
Xin the definitions above. The default justification is left.
X.PP
XVin determines what reference line of the text is positioned
Xat the output coordinate. The selection values are:
X.bp
X.BO
X0 - baseline (default)
X.EO
X.BO
X1 - half line
X.EO
X.BO
X2 - ascent line
X.EO
X.BO
X3 - bottom line
X.EO
X.BO
X4 - descent line
X.EO
X.BO
X5 - top line
X.EO
X.PP
XA common combination of alignments is left (0) and top line
X(5). This mode guarantees that all text output will lie to the
Xright and below the output coordinate. This corresponds with the
XAES object and GRECT coordinate systems.
X.PP

XFinally, the call to do the actual output is:
X.FB v_gtext()
Xv_gtext(vdi_handle, x, y, string);
X.FE
XX and y define the screen coordinate to be used as the alignment Xpoint. String is a pointer to a null terminated string, which Xmust be total eighty characters or less, exclusive of the null. XThis limit is imposed by the size of the intin[] array in the VDI Xbinding. Be warned that it is NOT checked in the standard Xbinding! Exceeding it may cause memory to be overwritten.
X.PP
XOne Inquire Function is useful with text output. The call
X.FB vqt_attributes()
Xvqt_attributes(vdi_handle, attrib);
X.FE
Xreads back the current attribute settings into the 10 word array Xattrib[]. The main items of interest are attrib[6] through Xattrib[9], which contain the width and height of characters, and Xthe width and height of the character cell in the current font. XYou should rely on this function to obtain size information, Xrather than using the output of the graf_handle() function. On Xthe ST, graf_handle() always returns sizes for the monochrome mode Xsystem font, which will be incorrect in the color screen modes.
X.PP
XAttrib[1] will contain the current graphics text color as set Xby vst_color(). Attrib[3] and [4] contain the horizontal and Xvertical alignment settings, respectively. Attrib[5] contains the Xcurrent writing mode, as set by vswr_mode().
X.SH OPTIMIZATION
XThe most common complaint about using bit maps Xfor character output is lack of speed. This section suggests ways Xto speed things up. By adopting all of these methods, you can Xrealize an improvement of two to three times in speed.
X.SH BYTE ALIGNMENT
XSince writing graphic text is essentially a Xbit-blit operation, characters which have "fringes", that is, do Xnot align evenly with byte boundaries, will suffer performance Xpenalities. The default system fonts in all resolutions of the ST Xare a multiple of eight pixels wide, so the problem reduces to Xassuring that each characters starts at a byte boundary in the Xscreen bit map. This will be true if the horizontal pixel address Xof the left edge of the character is evenly divisible by eight.
X.PP
XObviously, byte alignment is easiest to enforce when the Xhorizontal justification is right or left. Doing so with centered Xtext is possible, but requires adding padding blanks to odd length Xstrings.
X.PP
XWhen writing text within windows, it is helpful to assure Xthat the edges of the window working area are byte aligned. There Xis a section of code in the download which shows a technique for Xconverting a user requested window position and/or size to its Xworking dimensions, byte-aligning the width and horizontal

Xposition, and computing the adjusted external window coordinates.
X.SH WRITING MODE
XThe fastest text output mode is replace. All
Xother modes require reading in the target raster area and merging
Xit with the new information. You may find that you must use
Xtransparent or reverse transparent mode, for instance, to use or
Xpreserve an underlying background color other than white. In this
Xcase, you can still do some optimization by filling in the
Xbackground color for the entire string with a v_bar() call, rather
Xthan doing it one character cell at a time.
X.SH CLIPPING
XVDI output always proceeds faster when the
Xclipping rectangle is turned off, and text output is no exception.
XRemember that you may only do this if you are drawing into a
Xdialog box, or into the interior of a window which you know is on
Xtop. (You can use the WM_TOPPED and WM_NEWTOP messages for
Xkeeping track of the top window, or use the WF_TOP wind_get() call
Xto find the current top.) In both of these cases, you will know
Xthe width of the drawing area, and you can truncate the output
Xstring to fit exactly, rather than setting the clipping rectangle.
XFor this to work, you must have used the byte alignment technique
Xto assure that the width of the writing area is a multiple of
Xeight.
X.SH BINDINGS
XThe normal binding for v_gtext() is inefficient.
XIt copies the string which you supply character-by-character into
Xintin[] before it calls the VDI itself. In many cases, it will be
Xmore efficient for your application to place characters directly
Xinto intin[] and make the VDI trap call directly. To give you a
Xstart, the code for the standard v_gtext() binding has been
Xincluded in the download. When setting up intin[], be sure not to
Xload more than 80 characters, or you will probably crash the
Xsystem!
X.SH MOVING TEXT
XWhen performing text editing on the screen, you
Xshould avoid rewriting the string under edit whenever possible.
XIt is always more efficient to use the raster operations to move a
Xstring to the right or left, assuming that you have obeyed the
Xbyte alignment rule. If you are deleting characters, blit the
Xunchanged part of the screen to the left, and overstrike the last
Xcharacter in the string with a blank. If inserting characters,
Xblit the trailing portion of the string to the right before
Xwriting in the new character.
X.SH THAT'S IT FOR NOW
XThis concludes the two article series on
Xsimple VDI output. Future columns may explore more complex VDI
Xtopics such as proportional text. If there is something you would
Xlike to see, please use the Online Feedback to let me know!
XMeanwhile, the next column will give out the locations of some of
Xthe "hooks" and "trapdoors" built into the AES object structure,
Xincluding how to set up user-defined AES drawing objects.

X.PART XI GEM Hooks and Hacks
X.PP
XWelcome  to  the  eleventh episode of ST PRO  GEM,  which  is
Xdevoted to exploring some of the little documented,  but powerful,
Xfeatures  of GEM.   Like the authors of most complex systems,  the
XGEM  programmers left behind a set of "hooks",  powerful  features
Xwhich would aid them in enhancing the system later.  I am going to
Xlay  out  a number of these methods which have served me  well  in
Xmaking  creative use of the AES.   You will find that most of them
Xconcern  the object and form libraries,  since I was most involved
Xin those parts of GEM.  There are probably many more useful tricks
Xwaiting  to be found in other parts of GEM,  so if you happen onto
Xone, please let me know in the Feedback!  Before you begin,be sure
```

Xto pick up the download for this column: GMCL11.C in DL3 of PCS-X57.

X.SH POWERFUL OBJECTS

XThe first four tricks all involve augmenting standard AES Xobjects. This is a powerful technique for two reasons. First, Xyou can take advantage of the regular AES object and form Xlibraries to draw and handle most of your objects, so that your Xprogram need only process the exceptions. Second, you can use the XRCS to copy the special objects into multiple dialogs or Xresources. These four tricks are Extended Object Types, User-Xdefined Objects, TOUCHEXIT, and INDIRECT. Let's look at each of Xthem in turn.

X.SH EXTENDED OBJECT TYPES

XIf you look at the AES Object Library documentation, you will Xnotice that the values for the OB_TYPE field in an object are all X32 or less. This means that a number of bits are unused in this Xfield. In fact, the AES completely ignores the top byte of the XOB_TYPE field. In addition, the RCS ignores the top byte, but it Xalso preserves its value when an object is read, written, or Xcopied.

X.PP

XThis gives you one byte per object to use as you see fit. XSince the processing of an object or dialog is (so far) in the Xhands of the AES, the best uses of Extended Types are in flagging Xmethods for initializing an object or handling its value when the Xdialog completes.

X.PP

XFor example, you might have several dialogs containing Xeditable numeric fields. The Extended Type of each numeric field Xcould be set to the index of the corresponding value in an array. XThen your application's dialog initialization code could scan the Xobject tree for such objects, pick up the appropriate value Xfrom the array and convert it to ASCII, storing the result in the Xresource's string area. When the dialog was finished, another Xpass could be made to reconvert the ASCII to binary and store away Xthe results in the array. (Note that the map_tree() utility from Xcolumn #5 will scan an entire resource tree.)

X.PP

XAnother application is to assign uniform codes to exit Xbuttons in dialogs. If you give every "OK" button an Extended XType of one, and every "Cancel" button an Extended Type of two, Xthen you needn't worry about naming every exit object. Just Xexamine the Extended Type of the object returned by form_do, and Xproceed accordingly.

X.PP

XThe catch, of course, is that you have to find a way to enter Xthe Extended Type code in the first place. Version 1.0 of the XRCS, as shipped with the Atari developer's kit, makes no provision Xfor this. So you have your choice of two methods for creating the Xfirst object with each Extended Type code.

X.PP

XFirst, you can dump out a C source of a resource, insert the Xnew type code by hand, and regenerate the resource with STCREATE.

XAlternately, you could carefully modify the binary resource using XSID. You will probably want to reread the AES object manual, ST XPRO GEM #4 and #5, and use the C source as a guide when doing so. XIn both cases, you should make things easy on yourself by creating Xa one dialog resource with only a single object other than the Xroot. Version 2.0 of the RCS will let you directly enter an XExtended Type, but it has not yet been released for the ST by DRI.
X.PP
XOnce you have created a prototype extended object by either Xmethod, you can use the RCS to propogate it. The safest way is to Xuse the MERGE option to add the modified tree to the resource you Xare building. Then copy the prototype object via the clipboard to Xyour dialog(s), deleting the extra tree when you are done. If you Xare using several different extended objects, you can use MERGE Xand clipboard copies to get them all into one tree which will then Xbecome your own object library.
X.PP
XThe second way of using RCS is easier, but more dangerous. XIf you want to try the following technique, BACK UP YOUR RCS DISK XFIRST! Put simply, the RCS does not care what is in its dialog Xpartbox. It will make copies of anything that it finds there! This Xgives you the option of using the RCS on ITS OWN RESOURCE in order Xto add your customized objects to the partbox.
X.PP
XTo do this, open RCS.RSC from the RCS. Since there is no DEF Xfile, you will get a collection of question mark icons. Use the XNAME option to make TREE5 into a DIALOG. Open it, and you will Xsee the dialog partbox.
X.PP
XNow you can use the MERGE technique described above to insert Xyour customized objects. Then SAVE the modified resource, and Xrerun the RCS. Your new objects should now appear in the partbox. XIf you added several, you may have to stretch the partbox to see Xthem all. You can now make copies of the new objects just like Xany other part. (Note: DO NOT modify the alert or menu partboxes, Xyou will probably crash the RCS.)
X.SH USER-DEFINED OBJECTS
XThe one type of object which was not discussed in the earlier Xarticles on AES objects was G_USERDEF, the programmer defined Xobject. This is the hook for creating objects with other Xappearances beyond those provided by the standard AES. By the Xway, you should note that the G_PROGDEF and APPLBLK mnemonics used Xin the AES documents are incorrect; the actual names as used Xdefined OBDEFS.H are G_USERDEF and USERBLK.
X.PP
XThe RCS does not support the creation of G_USERDEF objects, Xsince it has no idea how they will be drawn by your program. XInstead, you must insert a dummy object into your resource where Xyou want the G_USERDEF to appear, and patch it after your Xapplication performs its resource load.
X.PP
XYou must replace the object's existing OB_TYPE with XG_USERDEF, though you may still use the upper byte as an Extended

XType. You must also change the OB_SPEC field to be a 32-bit Xpointer to a USERBLK structure. An USERBLK is simply two LONG X(32-bit) fields. The first is the address of the drawing code Xassociated with the user defined object. The second is an Xarbitrary 32-bit value assigned to the object by your application.
X.PP
XYou can designate objects for conversion to G_USERDEFs in the Xnormal fashion by assigning them names which are referenced one by Xone in your initialization code. You can also combine two tricks Xby using the Extended Type field as a designator for objects to be Xconverted to G_USERDEF. Each tree can then be scanned for objects Xto be converted. There is a short code segment in the download Xwhich demonstrates this technique.
X.PP
XMy usual convention is to define new drawing objects as Xvariants of existing objects, using the Extended Type field to Xdesignate the particular variation. Thus an Extended Type of one Xmight designate a G_BUTTON with rounded corners, while a value of Xtwo could flag a G_STRING of boldface text. When using this Xtechnique, the RCS can be used to build a rough facsimile of the Xdialog by inserting the basic object type as placeholders. The Xexisting OB_SPEC information can then be copied to the second Xposition in the USERBLK when the object is initialized.
X.PP
XOne final note before moving on: There is no reason that the XUSERBLK cannot be extended beyond two fields. You might want to Xadd extra words to store more information related to drawing the Xobject, such as its original type.
X.PP
XThe AES will call your drawing code whenever the G_USERDEF Xneeds to be drawn. This occurs when you make an objc_draw call Xfor its tree, or when an objc_change occurs for that object. If Xyour user-defined object is in a menu drop-drop, then your drawing Xcode will be called any time the user exposes that menu.
X.PP
XBefore getting into the details of the AES to application Xcalling sequence, some warnings are in order. First, remember Xthat your drawing code will execute in the AES' context, using its Xstack. Therefore, be careful not to overuse the stack with deep Xrecursion, long parameter lists, or large dynamic arrays. Second, Xthe AES is NOT re-entrant, so you may not make ANY calls to it Xfrom within a G_USERDEF procedure. You may, of course, call the XVDI. Finally, realize that drawing code associated with a menu Xobject may be called by the AES at any time. Exercise great care Xin sharing data space between such code and the rest of the Xapplication!
X.PP
XWhen your drawing code is called by the AES, the stack is set Xup as if a normal procedure call had occured. There will be one Xparameter on the stack: a 32-bit pointer to a PARMBLK structure. XThis structure lies in the AES' data space, so do not write beyond Xits end!
X.PP

XThe PARMBLK contains 15 words. The first two are the long
Xaddress of the object tree being drawn, and the third word is the
Xnumber of the G_USERDEF object. You may need these values if the
Xsame drawing code is used for more than one object at a time.
XWords four and five contain the previous and current OB_STATE
Xvalues of the object. If these values are different, your drawing
Xcode is being called in response to an objc_change request.
XOtherwise, the active AES call is an objc_draw.
X.PP
XWords six through nine contain the object's rectangle on the
Xscreen. Remember that you cannot call objc_offset within the
Xdrawing code, so you will need these values! The next four words
Xcontain the clipping rectangle specified in the active objc_change
Xor objc_draw call. You should set the VDI clip rectangle to this
Xvalue before doing any output to the screen.
X.PP
XThe last two words in the PARMBLK contain a copy of the extra
X32-bit parameter from the object's USERBLK. If you have followed
Xthe method of copying an OB_SPEC into this location, these words
Xwill be your pointer to a string, or BITBLK, or whatever.
X.PP
XWhen your drawing routine is done, it should return a zero
Xvalue to the AES. This is a "magic" value; anything else will
Xstop the drawing operation.
X.PP
XThe download contains a sample drawing routine which defines
Xone extended drawing object, a rounded rectangle button. You can
Xuse this procedure as a starting point for your own User Defined
Xobjects.
X.SH PUT ANYTHING YOU WANT ON THE DESKTOP!
XIn ST PRO GEM #2, I described the use of the WF_NEWDESK
Xwind_set call to substitute your own object tree for the normal
Xgreen desktop background. If the tree you supply contains User
XDefined objects, you can draw whatever you want on the desktop!
XSome of the things you might try are free hand drawings imported
Xin metafile format from EasyDraw, or whole screen bit images
Xgenerated by Degas. If you do the latter, you will have to store
Xthe entire image off screen and blit parts of it to the display as
Xrequested.
X.PP
XIn any case, remember that your desktop drawing code can be
Xcalled any time that a window is moved, so exercise the same care
Xas with a menu drawer. Also, be aware that making the WF_NEWDESK
Xcall does not force an immediate redraw of the desktop. To do
Xthat, do a form_dial(3) call for the entire desktop rectangle.
X.SH THE TOUCHEXIT FLAG
XThe TOUCHEXIT attribute is an alternative to the more usual
XEXIT. When the TOUCHEXIT bit is set in an object's OB_FLAG word,
Xthe form_do routine will exit immediately when the mouse button is
Xpressed with the cursor over the object. Your code can
Ximmediately take control of the mouse and display, without waiting
Xfor the release of the button. This method is used for generating
Xeffects such as slider bars within otherwise normal dialogs.

X.PP
XThe easiest way to code a TOUCHEXIT handler is to place a
Xloop around the form_do call. If the object number returned is
XTOUCHEXIT, then the animation procedure is called, followed by a
Xresumption of the form_do (WITHOUT recalling form_dial or
Xobjc_draw!). If the object returned is a normal EXIT, the dialog
Xis complete and control flows to the cleanup code.
X.PP
XThere is one idiosyncrasy of TOUCHEXIT which should be noted.
XWhen the AES "notices" that the mouse button has been pressed over
Xa TOUCHEXIT, it immediately retests the button state. If it has
Xalready been released, it waits to see if a double click is
Xperformed. If so, the object number returned by form_do will have
Xits high bit set. If you don't care about double clicks, your
Xcode should mask off this flag. However, you may want to use the
Xdouble click to denote some enhanced action. For example, the GEM
Xfile selector uses a double click on one of the file name objects
Xto indicate a selection plus immediate exit.
X.SH THE INDIRECT FLAG
XIf the INDIRECT bit is set in an object's OB_STATE word, the
XAES interprets the 32-bit OB_SPEC field as a pointer to the memory
Xlocation in which the ACTUAL OB_SPEC is to be found. Like User
XDefined objects, this capability is not supported by the RCS, so
Xyou have to set up the INDIRECT bit and alter the OB_SPEC at run
Xtime.
X.PP
XThe value of INDIRECT is that you can use it to associate an
XAES object with other data or code. The general technique is to
Xset up a table with a spare 32-bit location at its beginning.
XThen, when initializing the application's resource, you move the
Xtrue OB_SPEC into this location, set the INDIRECT flag, and
Xreplace the OB_SPEC field with a pointer to the table. The object
Xbehaves normally during drawing and form handling. However, if you
Xreceive its number from form_do or objc_find, you have an
Ximmediate pointer to the associated table, without having to go
Xthrough a lookup procedure.
X.PP
XThis technique works well in programs like the GEM Desktop.
XEach G_ICON object is set up with INDIRECT. Its OB_SPEC goes to
Xthe beginning of a data area defining the associated file. The
Xblank location at the beginning of file table is filled up with
Xthe former OB_SPEC, which points to a ICONBLK.
X.PP
XYou can also combine INDIRECT with TOUCHEXIT when creating
Xobjects that must change when they are clicked by a user. For
Xinstance, a color selection box might be linked to a table
Xcontaining the various OB_SPEC values through which the program
Xwill cycle. Each time the user clicked on the box, the TOUCHEXIT
Xroutine would advance the table pointer, copy the next value into
Xthe dummy OB_SPEC location at the front of the table, and redraw
Xthe object in its new appearance.
X.PP
XA programmer who wanted to follow a truly object-oriented

X"Smalltalkish" approach could use the INDIRECT method to bind AES
Xdrawing object to tables of associated procedures or "methods".
XFor instance, one procedure could be flagged for use when the user
Xclicked on the object, one when the object was dragged, one for
Xdouble-click, and so on. If the table structure was capable of
Xindicating that the true method was stored in another table, a
Xrudimentary form of class inheritance could be obtained.
X.SH INSTANT CO-ROUTINES
XWe turn to the AES event and message system for this trick.
XWhile some languages like Modula 2 provide a method for
Ximplementing co-routines, there is no such capability in C.
XHowever, we can effectively fake it by using the AES event
Xlibrary.
X.PP
XAs already seen in an earlier column, an application can
Xwrite a message to its own event queue using the appl_write call.
XUsually, this is a redraw message, but there is nothing to prevent
Xyou from using this facility to send messages from one routine in
Xyour program to another. To set up co-routines using this method,
Xthey would be coded as separate procedures called from the
Xapplication's main event loop.
X.PP
XWhen one of the co-routines wanted to call the other, it
Xwould post a message containing the request and any associated
Xparameters into the application's queue and then return. The main
Xloop would find the message and make the appropriate call to the
Xsecond co-routine. It it was necessary to then re-enter the first
Xco-routine at the calling point, the original message could
Xcontain an imbedded reply message to be sent back when the request
Xwas complete. A simple switch structure could then be used to
Xresume at the appropriate point.
X.PP
XThere are two potential problems in using this method. The
Xfirst is the limited capacity of the application event queue. The
Xqueue contains eight entries. While the AES economizes this
Xspace by merging redraws and multiple events, it cannot merge
Xmessages. Because of this limit, you must be extremely careful
Xwhen one message received has the potential to generate two or
Xmore messages sent. Unless this situation is carefully managed,
Xyou can get a sort of "cancer" which will overflow the queue and
Xprobably crash your application.
X.PP
XThe second danger involves race conditions. Message sent by
Xthe application are posted to the end of the queue. If other
Xevents have occurred, such as mouse clicks or keyboard presses,
Xthey will be seen and processed ahead of the application generated
Xmessage. This implies that you cannot use this method if the
Xprogram must complete its action before a new user generated event
Xcan be processed.
X.SH THAT'S ALL FOR NOW
XHopefully these hints will keep you profitably occupied for a
Xwhile. ST PRO GEM number twelve will return to the topic of user
Xinterfaces. Reaction to the first article on this subject was

```
Xmostly  positive,  but a lot of folks wanted to see real  code  as
Xwell.   In response to your feedback,  there will also be code for
Ximplemented  your  own "mouse sensitive" objects  which  highlight
Xwhen the cursor touches them.   This will be presented as part  of
Xan alternate form manager.
X.SH UPDATE: ATARI ST
XI  have  recently gotten more  information  on  some  topics
Xmentioned in earlier articles.   These notes will bring you up  to
Xdate:
X.PP
XA number of developers reported that they were unable to get
Xthe  self-redraw  technique described in ST PRO GEM  #2  to  work.
XThis is usually due to a bug in the appl_init binding in Alcyon C.
XThe  value  returned from the function,  which would  normally  be
Xassigned  to gl_apid,  is coming back as garbage.   To work around
Xthe problem,  declare EXTERN WORD gl_apid;  in your program and DO
XNOT  assign the value from appl_init.   The binding WILL make  the
Xassignment.  A tip of the hat to Russ Wetmore for this report.
X.PP
XThe   last   column   mentioned   that   turning   off   the   clip
Xrectangle  while drawing graphics text will speed things  up.   It
Xturns  out that the VDI will also run at the non-clipped speed  if
Xthe  ENTIRE  string  to  be written is  within  the  current  clip
Xrectangle.  To compound the problem, there is a one-off bug in the
Xdetection  algorithm  for  the right  edge.   That  is,  the  clip
Xrectangle  has to be one pixel BEYOND the right edge of  the  text
Xfor the fast write to work.
X.PP
XThe Feedback in ST PRO GEM #10 mentioned that there are known
Xbugs  in  the  Alcyon C floating point  library.   In  fact,  this
Xlibrary  has been replaced with a new,  debugged version in recent
Xshipments  of the Toolkit.   If you need to use floating point and
Xhave  run into this bug,  you should be able to get an update from
XAtari.   Also,  check  the  Atari  Developer's SIG (PCS-57) for  a
Xpossible download.
X.PP
XIn addition, it turns out there is an undocumented feature in
XAlcyon  C  which allows you to imbed assembly code  in-line.   Try
Xusing:
X.FB asm()
Xasm(".....");
X.FE
Xwhere the dots are replaced with an assembly instruction.  You get
Xone instruction per asm(),  one asm() per line.  Thanks to Leonard
XTramiel for both of the above tidbits.

X.PART XII GEM Events and Program Structure
X.PP
XSo I fibbed a little.  This issue (#12) of ST PRO GEM started
Xout to be another discussion of interface issues.  But, as Tolkien
Xonce said, the tale grew in the telling, and this is now the first
Xof  a series of three articles.   This part will discuss AES event
Xhandling  and  its implications for GEM  program  structure.   The
Xfollowing  article will contain a "home brew" dialog handler  with
Xsome  new  features,  and  the third will,  finally,  take up  the
Xdiscussion  of  interface design,  using the dialog handler as  an
Xexample.   (There is no download for this article.   The downloads
Xwill return, with a vengeance, in ST PRO GEM #13.)
X
X.SH ALL FOR ONE, AND ONE FOR ALL.
XA quick inspection of the AES
Xdocuments  shows that there are five routines devoted  to  waiting
Xfor individual types of events, and one routine, evnt_multi, which
Xis  used  when more than one type is desired.   This article  will
Xdiscuss  ONLY evnt_multi for two reasons.   First,  it is the most
```

Xfrequently used of the routines. Second, waiting for one type of Xevent is a bad practice. Any event call turns the system over to Xthe AES and suspends the application and its interaction with the Xuser. In such cases, some "escape clause", such as a timer, Xshould be inserted to revive the program and prompt the user if no Xevent is forthcoming. Otherwise, the application may end up Xapparently (or actually) hung, with a resulting reboot, and Xprobably a very annoyed user.
X.SH STARTING AHEAD.
XOne possible type of event is a message.
XMessages are usually sent to the application by the AES, and are Xassociated with windows or the menu. Two previous articles in Xthis series have discussed such messages. ST PRO GEM number two Xconsidered window messages, and number seven handled menu Xmessages. You may want to review these topics before proceeding.
X.PP
XThe actual evnt_multi call is a horrendous thing:
X.FB evnt_multi()
Xev_which = evnt_multi(ev_flags,
X   btn_clicks, btn_mask, btn_state,
X   r1_flags, r1_x, r1_y, r1_w, r1_h,
X   r2_flags, r2_x, r2_y, r2_w, r2_h,
X   &msg_buff,
X   time_lo, time_hi,
X   &mx, &my, &btn, &kbd, &char, &clicks);
X.FE
XEach of the lines in the call relate to a different event, and Xthey will be discussed in the order in which they appear.
X.PP
XNote that a call with this number of parameters causes some Xoverhead stacking and retrieval of the values. In most Xcases, this should be of little concern on a machine as fast as Xthe ST. However, where throughput is a concern, such as in close Xtracking of the mouse cursor, you may want to write a customized Xbinding for evnt_multi which dispenses with the parameter list. XThis can be accomplished by maintaining the values in a static Xarray and moving them as a block into the binding arrays int_in X(for all values but &msg_buff), and addr_in (for &msg_buff). Note Xthat you may NOT simply leave the values in int_in; other AES Xbindings reuse this space.
X.PP
XEv_flags and ev_which are both 16-bit integers composed of Xflag bits. Bits set in ev_flags determine which event(s) the call Xwill wait for; those set in ev_which indicate what event(s) Xactually occurred. Both use the following flag bit mnemonics and Xfunctions:
X.BO
X   0x0001 - MU_KEYBD - Keyboard input
X.EO
X.BO
X   0x0002 - MU_BUTTON - Mouse button(s)
X.EO
X.BO

```
X     0x0004 - MU_M1 - Mouse rectangle #1
X.EO
X.BO
X     0x0008 - MU_M2 - Mouse rectangle #2
X.EO
X.BO
X     0x0010 - MU_MESAG - AES message
X.EO
X.BO
X     0x0020 - MU_TIMER - Timer
X.EO
X.sp 1
XThe  appropriate mnemonics are ORed together to create the  proper
Xev_flags value.
X.PP
XThere  is  one  common pitfall here.   Notice  that  multiple
Xevents  may  be reported from one evnt_multi.   Event  merging  is
Xperformed  by the AES in order to save space on the  application's
Xevent queue.   If events have been merged,  more than one bit will
Xbe  set in the ev_which word.   Your application must check ALL of
Xthe  bits  before  returning to a new  evnt_multi  call.   If  you
Xdon't do this, some events may be effectively lost.
X.PP
XThe  first event to be considered is the mouse button.   This
Xis probably the most difficult event to understand and use, and it
Xhas one major shortcoming.
X.PP
XThe  parameter  btn_clicks tells GEM the  maximum  number  of
Xclicks which you are interested in seeing.   This value is usually
Xtwo,  if your program uses the double-click method, or one if only
Xsingle  clicks  are used.   The AES returns the number  of  clicks
Xwhich caused the event through &clicks, which must be a pointer to
Xa word.
X.PP
XGEM determines the number of clicks by the following  method.
XWhen the first button-down is detected, a time delay is begun.  If
Xanother  complete button-up,  button-down cycle is detected before
Xthe time expires,  then the result is a double click.   Otherwise,
Xthe  event is a single click.    Note that the final state of  the
Xbuttons  is  returned via &btn,  as described below.   By checking
Xthis  final state,  you may determine whether a single click event
Xended with the button up (a full click),  or with the button still
Xdown  (which  may  be  interpreted as  the  beginning  of  a  drag
Xoperation).   Double clicking is meaningless,  and not checked, if
Xthe evnt_multi is waiting on more than one button (see below).
X.PP
XThe double-click detection delay is variable,  and may be set
Xby your program using the call
X.FB ev_dclick()
Xev_dspeed = ev_dclick(ev_dnew, ev_dfunc);
X.FE
XEv_dfunc  is a flag which determines the purpose of the call.   If
Xit  is  zero,  the  current  double click  speed  is  returned  in
```

Xev_dspeed. If ev_dfunc is non-zero, then ev_dnew becomes the new Xdouble-click speed. Both ev_dspeed and ev_dnew are words Xcontaining a "magic number" between zero and four. Zero is the Xslowest (i.e., longest) double-click, and four is the fastest. X(These correspond to the slow-fast range in the Desktop's XPreferences dialog.) In general, you should not reset the click Xspeed unless specifically requested, because such a change can Xthrow off the user's timing and destroy the hand/eye coordination Xinvolved in using the mouse.
X.PP
XGEM was originally designed to work with a single button Xinput device. This allows GEM applications interaction well with Xdevices such as light pens and digitizing tablets. However, some Xfeatures are available for dealing with multi-button mice like the XST's.
X.PP
XThe evnt_multi parameters btn_mask and btn_state are words Xcontaining flag bits corresponding to buttons. The lowest order Xbit corresponds to the left-most button, and so on. A bit is set Xin the btn_mask parameter if the AES is to watch a particular Xbutton. The corresponding bit in btn_state is set to the value Xfor which the program is waiting. The word returned via &btn Xuses the same bit system to show the state of the buttons at Xcompletion. It is important to notice that all of the target Xstates in btn_state must occur SIMULTANEOUSLY for the event to be Xtriggered.
X.PP
XNote the limiting nature of this last statement. It prevents Xa program from waiting for EITHER the left or right button to be Xpressed. Instead, it must wait for BOTH to be pressed, which is a Xdifficult operation at best. As a result, the standard mouse Xbutton procedure is practically useless if you want to take full Xadvantage of both buttons on the ST mouse. In this case, your Xprogram must "poll" the mouse state and determine double-clicks Xitself. (More on polling later.) By the way, many designers X(myself included) believe that using both buttons is inherently Xconfusing and should be avoided anyway.
X.SH MOUSE RECTANGLES.
XOne of GEM's nicer features is its ability
Xto watch the mouse pointer's position for you, and report an event Xonly when it enters or departs a given screen region. Since you Xdon't have to track the mouse pixel by pixel, this eliminates a Xlot of application over. The evnt_multi call gives you the Xability to specify one or two rectangular areas which will be Xwatched. An event can be generated either when the mouse pointer Xenters the rectangle, or when it leaves the rectangle. The "r1_" Xseries of parameters specifies one of the rectangles, and the X"r2_" series specifies the other, as follows:
X.sp 1
X.ti +2
Xr1_flag, r2_flag - zero if waiting to enter rectangle,
X.br
X.ti +2

X   one if waiting to leave rectangle
X.br
X.ti +2
Xr1_x, r2_x - upper left X raster coordinate of wait rectangle
X.br
X.ti +2
Xr1_y, r2_y - upper left Y raster coordinate of wait rectangle
X.br
X.ti +2
Xr1_w, r2_w - width of wait rectangle in pixels
X.br
X.ti +2
Xr1_h, r2_h - height of wait rectangle in pixels
X.br
X.sp 1
XEach rectangle wait will only be active if its associated flag
X(MU_M1 or MU_M2) was set in ev_flags.
X.PP
XThere are two common uses of rectangle waits. The first is
Xused when creating mouse-sensitive regions on the screen. Mouse-
Xsensitive regions, also called "hot spots", are objects which show
Xa visual effect, such as inversion or outlining, when the mouse
Xcursor moves over them. The items in a menu dropdown, or the
Xinversion of Desktop icons during a drag operation, are common
Xexamples.
X.PP
XHot spots are commonly created by grouping the sensitive
Xobjects into one or two areas, and then setting up a mouse
Xrectangle wait for entering the area. When the event is
Xgenerated, the &mx and &my returns may be examined to find the
Xtrue mouse coordinates, and objc_find or some other search will
Xdetermine the affected object. The object is then highlighted,
Xand a new wait for exiting the object rectangle is posted. (ST
XPRO GEM #13 will show how to create more complex effects with
Xrectangle waits.)
X.PP
XThe second common use of rectangle waits is in animating a
Xdrag operation. In many cases, you can use standard AES animation
Xroutines such as graf_dragbox or graf_rubberbox. In other cases,
Xyou may want a figure other than a simple box, or desire to
Xcombine waits for other conditions such as keystrokes or
Xcollision with hotspots. Then you will need to implement the drag
Xoperation yourself, using the mouse rectangles to track the
Xcursor.
X.PP
XIf you want to track the cursor closely, simply wait for exit
Xon a one pixel rectangle at the current position, and perform the
Xanimation routine at each event. If the drag operation only works
Xon a grid, such as character positions, you can specify a larger
Xwait rectangle and only update the display when a legal boundary
Xis crossed.
X.SH MESSAGES.
XThe &msg_buff parameter of evnt_multi gives the

Xaddress of a 16 byte buffer to receive an AES message. As noted
Xabove, I have discussed standard AES messages elsewhere. The last
Xcolumn also mentioned that messages may be used to simulate co-
Xroutines within a single GEM program.
X.PP
XA further possibility which bears examination is the use of
Xmessages to coordinate the activities of multiple programs. In
Xsingle-tasking GEM, at least one of these programs would have to
Xbe a desk accessory. In any such use of the GEM messages, you
Xshould pay careful attention to the possibility of overloading the
Xqueue. Only eight slots are provided per task, and messages,
Xunlike events, cannot be merged by the AES.
X.SH TIMER.
XThe timer event gives you a way of pacing action on
Xthe screen, clocking out messages, or providing a time-out exit
Xfor an operation. Evnt_multi has two 16-bit timer input
Xparameters, time_hi and time_lo, which are the top and bottom
Xhalves, respectively, of a 32-bit millisecond count. However,
Xthis documented time resolution must be taken with a grain of salt
Xon the ST, considering that its internal clock frequency is 200Hz!
X.PP
XThe timer event is also extremely useful for polling the
Xevent queue. A "poll" tests the queue for completed events
Xwithout going into a wait state if none are present. In GEM, this
Xis done by generating a null event which always occurs
Ximmediately. A timer count of zero will do just that.
X.PP
XTherefore, you can poll for any set of events by specifying
Xthem in the evnt_multi parameters. A zero timer wait is then
Xadded to ensure immediate completion. Upon return, if any eveit(s) OTHER than
MU_TIMER are set, a significant event was found
Xon the queue. If only MU_TIMER is set, the poll failed to find an
Xevent.
X.SH KEYBOARD.
XThere are no input parameters for the keyboard
Xevent. The character which is read is returned as a 16-bit
Xquantity through the &char parameter. For historical reasons, the
Xcodes which are returned are compatible with the IBM PC's BIOS
Xlevel scan codes. You can find this character table in Appendix D
Xof the GEM VDI manual. In general, the high byte need only be
Xconsidered if the lower byte is zero. If the low byte is non-
Xzero, it is a valid ASCII character.
X.PP
XEvnt_multi also returns the status of several modifier keys
Xthrough the &kbd parameter. This word contains four significant
Xbits as follows:
X.BO
X   0x0001 - Right hand shift key
X.EO
X.BO
X   0x0002 - Left hand shift key
X.EO
X.BO

X   0x0004 - Control key
X.EO
X.BO
X   0x0008 - ALT key
X.EO
X.sp 1
XIf a bit is one, the key was depressed when the event was
Xgenerated. Otherwise, the key was up. Since the state of these
Xkeys is already taken into account in generating the &char scan
Xcode, the &kbd word is most useful when creating enhanced mouse
Xfunctions, such as shift-click or control-drag.
X.SH RANDOM NOTES ON EVENTS.
XAlthough the &mx, &my, &btn, and
X&kbd returns are nominally associated with particular event types,
Xthey are valid on any return from evnt_multi, and reflect the last
Xevent which was merged into that return by the AES. If you want
Xmore current values, you may use graf_mkstate to resample them.
XWhichever method you choose, be consistent within the application,
Xsince the point of sampling has an effect on mouse and keyboard
Xtiming.
X.PP
XAlthough this and preceding columns have been presented in
Xterms of a GEM application, the event system has many interesting
Ximplications for desk accessories. Since the AES scheduler uses
Xnon-preemptive dispatching, accessories have an event priority
Xeffectively equal to the main application. Though "typical"
Xaccessories wait only for AC_OPEN or AC_CLOSE messages when in
Xtheir quiescent state, this is not a requirement of the system.
XTimer and other events may also be requested by an accessory.
X(Indeed, there is no absolute requirement that an accessory
Xadvertise its presence with a menu_register call.) The aspiring
XGEM hacker might consider how these facts could be used to create
Xaccessories similar to "BUGS" on the Mac, or to the "Crabs"
Xprogram described in the September, 1985 issue of Scientific
XAmerican.
X.SH EVENTS AND GEM PROGRAM STRUCTURE.
XAlthough the evnt_multi
Xcall might seem to be a small part of the entire GEM system, its
Xusage has deep implications for the structure of any application.
XIt is generally true that each use of evnt_multi corresponds to a
Xmode in the program. For instance, form_do contains its own
Xevnt_multi, and its invocation creates a moded dialog. While the
Xdialog is in progress, other features such as windows and menus
Xare unusable. The graf_dragbox, graf_rubberbox, and graf_slidebox
Xroutines also contain evnt_multi calls. They create a mode which
Xis sometimes called "spring-loaded", since the mode vanishes when
Xsome continuing condition (a depressed mouse button) is removed.
X.PP
XIn consequence, a well-designed, non-modal GEM program will
Xcontain only one explicit evnt_multi call. This call is part of a
Xtop-level loop which decodes events as they are received and
Xdispatches control to the appropriate handling routine. The
Xdispatcher must always distinguish between event types. In

```
Xprograms  where  multiple windows are used,  it may also  need  to
Xdetermine which local data structure is associated with the active
Xwindow.
X.PP
XThis  construction  is  sometimes  called  a  "push"  program
Xstructure,  because  it  allows the user to drive the  application
Xby generating events in any order.  This contrasts with the "pull"
Xstructure of traditional command line or menu programs,  where the
Xapplication is in control and demands input at each step before it
Xproceeds.    "Push"  structure  promotes  consistent  use  of  the
Xuser interface and a feeling of control on the part of the user.
X.PP
XThe  next ST PRO GEM column will look more closely at  events
Xand  program  structure in the context of a large piece  of  code.
XThe  code  implements an alternate dialog  handler,  incorporating
Xmouse-sensitive objects as part of the standard interface.   Since
Xthis  code  is  "open",  it may be modified and  merged  with  any
Xapplication's main event loop, resulting in non-modal dialogs.

> change the resolution (including itself). This is version 0.95
> Intersect Ramdisk: From Florida, allows the use of drive c, d, e, but not
> at the same time. Shows free memory (which doesn't work right all the
> time), and allows you to reallocate without losing bytes (per
> GEMDOS bug). I have found this to be nice, but I have had troubles
> with it. Also a desk accesory.
> Various ramdisks labeled RMDK709, RMDK300...: These install themselves as
> Desk accesories, and are there all the time, ie. you boot with it

and it is present. Not deselectable, but they are small programs.
Mike's and Intersect allow you to allocate a ramdisk of any size up to
the extent of your memory. Mine is about 8K, Intersect is 12K with a
2K resource file that must be used with it.

Non-public domain ramdisks include (the first) MDisk (by michtron)
program once and it sets up a ramdisk. You can run it as many tim
run the program once for drive C, twice to add drive D, etc. Use very little
ram space since it does a terminate and stay resident call to protect the
read/write vectors. You can not change the resolution at all.
Duto folder... ok...
When you use copy2.prg, which transfers file to a ramdisk, you can have files
Dmatically into the ramdisk when you boot up, and after you allocate
the ramdisk.
A-ram (from Antic): another from the desk accesories... from what I heard it
is alright...
Solar-Ram: who knows... supposedly the entire solar-pak with all its utilities
is pretty nice (that's what I heard)
So many others, it's not worth commenting on. Depending on what you want to do
you can best decide for yourself what the best ramdisk is for you.

My next version will put the icon onto the desktop for you, assuming I have
found the way to do it (I can do it from SID)...

On another note, are there any execs for the AS/9000N out there that can make
receiving all these reader files easier. They contain so much junk in the
header that it is a pain to receive and edit them. We use
VM/SP 2.1, but will be switching to VM/SP 4.0 very soon, now.

Also, is there a way to transfer files (binary or otherwise) via BITNET?
I would be willing to send my latest version, as binary.
And, where do I get the articles listed in some of the letters, and what
file servers at where have related info? (as you can tell, I'm a nubie...)
Sorry if you got my previous message and it was junked, I am using a primitive
exec for sending mail via BITNET, and it can only be used in the line mode, and
I input all of the text as the 'Subject' (oh boy...).
From Houston,
Michael Vederman

Keywords: date
Summary: Setting the date takes time to become effective.

There have been several complaints that programs that set the time and
date do not work. I hve written some that do, but it takes time for
them to become effective. If you use setdate() and then mouse the
control panel the date and time are not changed, but after about a
minute they jump to their correct values. I have my date program in an
AUTO folder and it works fine. By the way, AUTO is read before the
desktop, so if you have a colour monitor the program will run in low res.

Avila Associates just got an Atari hard disk so if you have a benchmark
program that you feel appropriate to answer that question please mail
it to me and I will try to get an answer.

If it has to wait for us to write a test it may take a while.

Keywords: (but not the Mandelbrot set)

Here is the source code for the uuencoded file 'levy.ttp' posted previously:
```
------------------------------------------------------------------------
/*
 * levy.ttp:  Brownian Relief Fractal Generation Program for the Atari 520ST
 *
 * This program is distributed in the public domain with no restrictions on
 * its use.
 *
 * The algorithm implemented herein is described in B. B. Mandelbrot "Fractals:
 * Form, Chance, and Dimension" (Freeman 1977) p. 207. It was first defined
 * by P. Levy "Processus Stochastiques et Mouvement Brownien" (Paris:
 * Gauthier-Villars 1948).
 *
 * program author: J. M. Knapp  AT&T Bell Labs   Columbus OH  (cbosgd!nscs!jmk)
 *
 * Background (from Mandelbrot):
 *
 * [The Brownian model of the landscape] finally provides us with our
 * long-sought example of a curve that (a) is devoid of self intersections,
```

```
 * (b) is practically devoid of self contacts, (c) has fractal dimension
 * clearly greater than 1, and (d) is isotropic.
 *
 * More precisely, the dimension of these coastlines is 3/2, which is of
 * course much higher than most of Richardson's values [e.g. 1.26 for the
 * coast of Britain]. The Brownian artificial coastline is therefore
 * limited in its applicability. It recalls northern Canada, Indonesian
 * Islands, perhaps western Scotland, and the Aegean. It is applicable to
 * other examples as well, but certainly not to all.
 *
 * It is a pity, because a relief of dimension D=5/2 and coastlines of
 * dimension 3/2 would have been easy to explain. Indeed, the Brown-Levy
 * function is an excellent approximation of the relief that would have
 * been created by superimposing independent rectilinear faults.  The
 * generative model proceeds simply as follows. Starting with a horizontal
 * plateau, break it along a straight line chosen at random to introduce
 * a kind of cliff, a random difference between the levels of the two
 * sides of the break. Then start all over again, ad infinitum. The
 * process merely generalizes the Poisson process. With no need for
 * mathematical or physical details, we can see that the argument seizes
 * at least one aspect of tectonic evolution...
 *
 * From B.B. Mandelbrot "Fractals: Form, Chance, and Dimension"

Is Dayton close enough? Try the Webbed Sphere at (513)299-3665, or there's always The Underground, (513)433-3232. Both are 300/1200 baud, 24hrs.

If there's anything in particular you are looking for I would be willing to transfer it to you. It's your dime.

Well, I just got the 520ST and so far I'm very impressed. I've been mostly using the vt52 emulator to work on a VAX at the office, and the text display is absolutely gorgeous (I have the monochrome system) - razor sharp and steady as a rock. I don't think Atari emphasizes this enough in their ads - I'd say this is the easiest display on the eyes short of a sun. Anyway, I have a few questions -

Could someone who has a good termcap entry for the vt52 emulator built in to the ST email it to me?

Is kermit, or some package that supports the kermit file transfer protocol, available for the ST?

I'm looking for a good C compiler for the ST so I can start hacking! I'd like any comments and/or minireviews from people who are using compilers. I guess the obvious choice is to order the development system from Atari. Is there any glaring reason not to do this? Things that would prevent me from ordering it include:
It does not support the full C language.
It has serious bugs.
It has stupid limits, i.e. 52 cases per switch, 634 characters per macro, etc.

My new ST520 has a composite video out. I haven't tried it yet, but I'm sure
it must work. I got my ST wednesday, April 30. I'm sure someone will come
out with a mod for prior rev owners. Maybe Jerry Ciarcia or one of the
look-alike authors will put it out, or perhaps some concerned soul at

Atari could *unoffically* post upgrade instructions.

I spent this weekend with my brother-in-law who has a 520ST, and we came up
with some questions I hope someone can answer:

1) Are TOS-in-ROM chips available to users?

2) Does protected software cause problems with the disk drives? He has a
   DSDD drive (314??) that has serious problems copying FINAL WORD (the manual
   says to make backup copies). Occasionally he has to try two or three times
   to copy a disk that is *not* protected (eg backing up ZORK I).

3) Are there any instruction manuals for NEOCHROME available? We got a free
   copy from the local (Jax, FL) Games 'n Gadgets (I think it's v0.5), but
   no instructions.

4) Is there a Jax FL user group for 520ST's?

5) Is there a compilation of public-domain or free software for the 520ST?

Thanks for any information. Please mail directly to moore@ncsc, as I'm not
on this list (yet!)

~~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~~~~

a while back someone asked if you could use asm code in DRI C, the
answer is yes, but referencing variables is a pain, the only way i've
found is to declare the variables extern as in

```
extern int fred;
.
.
asm("    pea  ~fred");
```

anyone know of a better way ?????

If one does not want to use the default coordinate system used to plot into a window (upper left is 0,0), is there a way of changing this coordinate system. For example, I want to use a cartesian coordinate system with the center "midwindow". Any information describing how to do this would be much appreciated.

I think the main reason is twofold -- firstoff, a machine like the MAC was apparently conceived as more of a closed appliance computer, and as such didn't require a REAL operating system; it only has the MAC graphics environment to work with. As for there being no accepted standard 68000 operating system (which today seem a logical thing, especially considering there are people using MACs for development who could really benefit from a conventional CLI), that's mainly why none of the current big 3 used any one system (MAC didn't have one, and the Amiga and ST were developed concurrently. Though why the ST couldn't stick to standard CP/M-68K I don't know). Anyway, UN*X would have been nice on all machines, and as well my perference, but it wouldn't lend itself well to a basic 68000 based machine -- its too big to run completely from floppies, it like demand paged virtual memory, etc. Now if we had a minimal system with 10 Meg hard drive, 68010, and some MMU or other, then we'd be talking UN*X (or we'd be fools if we weren't).

As for these machines being locked into their current OSs, that's probably true from the point of view of machine specific support; not that you couldn't write an OS-9 graphics shell that made Intuition calls, I just don't think its likely to be commercially supported. But like the workstation market, I think that the current manufacturers might decide sooner or later to support a standard OS (if an acceptable one emerges), just like Apollo has decided to also offer UN*X in addition to its propriatary Ageis OS.

>just piggy back the same way as with the 1 Meg upgrade.

You could convert either the 520 or the 1040 to up to 4 meg using
1 meg chips or 1 meg hybrid chips (about $30 each now). IF there
were 18 pins in the RAM sockets, OR there were a header near the
MMU, OR there were an adapter to get the necessary lines out of
the MMU between the chip and the socket, OR ...

BUT, you will have to pull out ALL of the old RAM and replace with
1 meg chips. When they mentioned how trivial it would be to upgrade
the 1040 to 2 or even 4 meg, they were talking about how trivial it
would be for ATARI to create a NEW IMPROVED PRODUCT.

From the information I have been able to get, it looks like there is
practically NO DIFFERENCE between the two, except that the 1040 has
more memory and the internal drive and power supply. If having the
internal drive (and fewer cables, power supplies,...) sounds desirable,
or having the 1Meg right from the start without losing your warranty
sounds good, then get the 1040. If you want to save a few dollars, get
the 520.

There is also the question of whether you should USE the extra
memory, and how.

If you want a RAM DISK, you could put one on the DMA interface. In
fact, if Atari comes up with an SCSI interface, there are several such
"drives" ranging from 1MB to 65MB. A RAM CACHE could also be installed
externally. Putting "memory resident accessories" in ram is just
a Kludge for real multi-tasking which could be better served by

a real multi-tasking OS. A "does everything" application such as
a "1-2-3" type package is yet another kludge which could be better
served in other ways. An extra-large program that REQUIRES 1 Meg,
such as GNU emacs or some equally large monster, won't run on the
smaller machines.

It would be nice if Atari could come up with an upgrade "MMU" chip
that could realy do "memory management" such as demand paging,
relocation, and protection, or maybe use the 68070 chip with it's
built in MMU. Of course one could always make a "hot rod" computer
using any of these techniques :-). Maybe they will AT LEAST put
a SOCKET under the 68K chip so that the MMU and CPU could be upgraded
later on.

At least the ST is relatively easy to upgrade :-).

Keywords: 520ST, C language

I've had the Lattice C compiler for the 520ST (from METACOMCO for $150
U.S., list) for several weeks and have a few impressions to report.

1) though the supplied editor appears useful, it is different enough
from common editors (vi, emacs, or wordstar) that I haven't used it.

2) Lattice C does appear to follow K&R very closely, but I have found a
few things it doesn't like that other C compilers do. Fortunately, it
was easy to program around those things.

3) METACOMCO expended a lot of effort in creating a package that runs on a
"small" computer system. That is, I was able to compile all of the
PCHACK sources with 1 single sided drive on a 512K ST (TOS in ROM) with a RAM
disk sized to hold just the compiler and standard header files (because
PCHACK is so large and the compiler generates large intermediate files,
I had to place the sources on 5 disks). The compiler is broken into two
programs (passes), each around 88K in size, which communicate via a file

of intermediate code (quadruples). Combined with the separate compilation facilities of C, this makes it possible (though inconvenient) to compile some large programs.

4) the package is not integrated into a command interpreter (as is Personal Pascal or Hippo C), so you can run the compiler from the desktop or any other command interpreter you desire. It is arguable if this is a benefit or not, but I have the freedom to chose my own shell. The tradeoff is that the integrated packages make it easy to go from a syntax error to editing.

5) the supplied libraries provide enough of the UNIX(tm) Operating System feeling to be familiar (i.e. stdio.h, math.h, setjmp.h, etc.) and they allow stdin and stdout to be redirected (but no pipes).

6) the documentation will not teach the C language or how to program in a GEM environment, but are adequate for an experienced C programmer. There is very little on how to access GEM, the BIOS, or XBIOS, so other guides are mandatory to take full advantage of the 520.

7) the linker is very powerful, operating in interactive or batch mode. In the latter, one can generate a very long list of files and libraries to link, longer than one's memory will permit.

8) finally, there is error handling by both the compiler and linker. Only the first pass of the compiler does a decent job of error handling. It tells you the error and the source line it was found on, so you have an idea of where to look (the first pass does the preprocessing and most of the compilation, generating intermediate code in the form of quadruples). The second pass (which does code selection on the quadruples, generating a relocatable code) and the linker (which pulls all the relocatable code into an executable image), do not seem to know about source lines and only report that files have errors. They don't give any indication of where in the file the problem is. One might accept this if the first pass caught all the errors, but it doesn't. In compiling PCHACK, the second pass found one error and the linker found a relocation error in about one out of every five files. I was able to guess on the pass 2 problem and fix it, but am out of luck on the linker problems. Needless to say, I am less than pleased with the Lattice package and am not recommending that anyone buy it until METACOMCO gets some things fixed (I should also note that I have compiled and linked several small programs successfully, so the package works some of the time). Since the Lattice C compiler is the compiler in the Amiga developer's kit, I expected these kinds of bugs to have been resolved.

9) compilation speed was nothing to cheer about, but can be improved by using a RAM disk for the compiler and source files (i.e. a 1Meg system with half Meg of RAM disk). The generated code was comparable in size to that of the Personal Pascal compiler (about half as big as the Hippo C). I have not performed any timing tests.

In summary, this product has potential, but save your money until it is fixed. I don't know what METACOMCO's update policy is, but expect

to soon find out. I also welcome responses from others who have had
other experiences with this product than I have.

Here is the set up:
I have set up \include and \bin directories and have all temp files
in a ram disk. Works great except for one thing; Can anyone tell me how
you get the linker to look in \lib for gemstart, vdibind, aesbind etc...
It does not seem to like path names on the command line!
       Thanks in advance...

==========
In the Toronto area, we get mixed reports on the reliability
of the double sided floppy drive (the one in the 1040). One specific
complaint is that a disk written on one drive may well not be
readable on another drive.
A suggestion was made thatthe heat from the internal power supply
on the 1040 might be causing dimensional changes in the drives.
Any comments from netland?

Hi,

I hope there are some peole out there with experience of ROM TOS and C. I have a 1040stf and have just bought Metacomco-Lattice C.

I have a few questions that are bothering me:

1. Why, in all the examples I have seen (C manual, "Gem on the Atari ST", "Anatomy of Atari ST" ..) do they use 'forward slashes' (a la UNIX) as directory separators. I have tried in vain to use these, but my computer will only accept 'back slashes' (a la MSDOS).

2. In the linker section of the Lattice C manual, and the supplied C.LNK file, there is a line of the form

```
    INPUT *
```

which is supposed to read in the .BIN file specified on the command line. I wish to keep the source files and compiler/linker in separate directories, and so have changed that to read

```
    INPUT \src\*
```

but this ignores the command line. It will load in the alphabetically first .BIN file in the \src\ directory. Is this a bug? Does anyone have a work-around for it?

3. I have been trying to get to grips with window handling. As a first attempt I typed in the AESC01.C example from "GEM on the Atari ST". This crashed with two bombs as written. I had already copied the supplied "gemlib.h" to "gemdefs.h" as required, and used short (16 bit) integers for all the parameters. After some playing with it, and reading the "Professional GEM" article posted here a few months ago, I have now got it to compile, link, and run. But it steadfastly refuses to put a name on the move bar. The current state of my program is given below.

If anyone can help with these problems, I would appreciate news or mail.

Cheers,
Frank.

```
---------------------cut here---------------------------------------
/*
 * "AESC01.c" AES Window example from
 *   "GEM on the Atari ST", First Publishing, pp388-390
 *
 * Implemented into lattice C by F K Carver, 4 May 1986
 * Refused to run (2 bombs) as written. mods started 5 May 1986
 * Now compiles and runs but doesn't show a window name.
*/

#include "gemdefs.h"
typedef short INT; /* Lattice C uses 16 bit shorts and 32 bit ints */

INT contrl[12], intin[128], ptsin[128], intout[128], ptsout[128];
INT work_in[12], work_out[57];
INT handle, wi_handle;
INT gl_hhbox, gl_hwbox, gl_hhchar, gl_hwchar;
INT xdesk, ydesk, wdesk, hdesk;

open_work()
{    INT i;

     appl_init();
     handle = graf_handle(&gl_hwchar, &gl_hhchar, &gl_hwbox, &gl=hhbox);
     for (i=0; i<10; work_in[i++]=1);
     work_in[10] = 2;
     v_opnvwk(work_in, &handle, work_out);
}

close_work()
{    gemdos(0x1);
     v_clsvwk(handle);
     appl_exit();
}

open_window();
{    INT parts = NAME| MOVER| FULLER| SIZER| CLOSER;

     wind_get(0, WF_WORKXYWH, &xdesk, &ydesk, &wdesk, &hdesk);
     wi_handle = wind_create(parts, xdesk, ydesk, wdesk, hdesk);
     wind_set(wi_handle, WF_NAME, "Untitled", 0,0);
     wind_open(wi_handle, xdesk, ydesk, wdesk, hdesk);
}

main()
{    open_work();
     open_window();
     close_work();
}

Hi,

Does anybody have any details of the desktop save format?

I have looked at it and played around to the extent of renaming the
dustbin, and would like to know more. For example, it seems that
setting up the colour map has no effect if the CONTROL.ACC accessory is
not loaded, but it must be stored in there somewhere. What about using
it from user programs?

Any help appreciated.
Cheers,
Frank.

I just bought Universe II from Omnitrend. I've played it for about
10 hours total and I think I've found a bug in the parser on disk C.
Whenever I try to talk to a game character, the parser responds with
"Huh?" a few times, than an alert box appears and informs me of a random
access error! This has happened twice now. Has anyone else experienced
the same thing?
By the way, my copy is Version 1.0 and I'm running it on a 520 ST with
the 1 meg upgrade, TOS in ROM.

  This morning I saw a posting for a termcap using a 'hi50 hack' that I assume, gets 50 lines on a mono system. I would really appreciate ANY pointers and/or the hack itself. As always, thanks in advance for any help.

I am new on the net, and I don't have the tools needed (whatever they are) to uuencode. There's some on Compuserve, adn the Atari BBS in Sunnyvale hase/ them, too. Maybe I could uuence/ode them If I Knew How... is there a doc file or something on it?

By the way, my mailer daemon is giving me fits over messages to you, so I presume you are getting these from the net instead of personally. Why does it do that?

Or it could just be that this darned UNIX system just doesn't like me. I'm going back to VMS.

That's right -- LINK68 does not like path names, and thinks backslash
is a comment or something in command files. We put libraries in the
root directory of a hard disk partition (usually C:, along with all
the executables). You /could/ do the same with a floppy.

I've had my ST for five months, been running with a homebrew 1 Mbyte upgrade for four, ROMs for one. On Sunday morning my power supply smelled burnt, and the ST was dead when I turned it on. Fortunately, when I tried a new power supply the machine was fine.

It was an old, black, tall power supply (with cables running out of both ends).

Question: I remember an article a few months back from someone whose old power supply failed, and mention of some acknowledgement of the problem by Atari. Is there an official line from Atari? (Probably "yes, you overheated your power supply with the extra RAM, you lose!")

Question: Has this happened to many of you? What did you do?

  I just got a replacement 520ST from a distributor today. The power
supply has the two cords on opposite sides of the brick. Is this
one of the old unreliable supplies?? If so, what was the problem
and more important, what was the fix?

In discussions with Paul Swanson of Nite Lite Systems (an Atari 520ST sales
and service -- and 1M upgrade) dealer, I became convinced that it would not be
very difficult to modify the 520ST to have a full CPU bus extension port
like the 8-bit 800XL has. All it would take would be to replace the existing
cartridge port connector with a larger one and add a small piggyback board
above it (or a "smart" connector on the cable) which provided buffers for the
extra address lines -- maybe for all address lines, which would make it
easier to do on the cable side of the connector. Because of the high speed of
the processor, one would of course have to be careful of cable length,
shielding, termination and such things, but I see no reason that it couldn't
be done.

This mod looks easy enough that I no longer consider the absence of a CPU bus
connection a telling blow in the 520ST versus AMIGA battle. The mod would
open the way, for example, to large memory expansions and other nifty things.

This is posted to all, but I really hope somebody from Atari
will respond.

Where/how might i get a set of diagnostics for my 520ST? I have
heard of cartridge-slot ROMs for this, but never seen anything
physical. Are they real? Can I get them?

(I am considering doing a 1 meg upgrade, but would like to have
an "official" diagnostic capability to determine that it has all
come up AOK.)

I guess it would be nice if Atari or DRI or someone would fix bugs like that.
It really is annoying to have a directory structure and be essentially unable
to use it properly. Us Unix people are used to something that is well thought
out and highly useable. (not perfect) Is Atari planning to do something about
problems with its environment? This would include what hearsay sez is a number
of memory allocation bugs. I guess what I'm trying to say is that these are
not huge bugs, they seem to be weekend fixes. Are we going to get any updates

as developers ever? Could we get a forecast of what we can expect?

I'd like to offer the following statistics/info on 520 and 1040
reliability based on our experiences.

  520ST: We took delivery on twelve 520ST's last Fall. One (1)
  keyboard/computer unit was VERY DOA. Our dealer (and on up the
  chain!) couldn't figure out how to fix it so they replaced the
  whole PC board. One (1) monitor was flaky -- probably a thermal
  problem. This was fixed.

  1040ST: We just took delivery on twelve (12!) 1040ST's last
  week. Six out of six work fine so far. We are about to unpack
  and test the other six, but I would anticipate only one failure
  based upon our earlier experience.

A few side comments are in order.

  1040ST availability. Units are out there. Finding them,
  ordering from a reliable dealer and getting them is another
  matter. Frankly Atari (Neil?), distibution in Ohio is a disaster.
  I can only encourage you to look into this situation as a large
  market is currently going unsatisfied. If a big advertising
  push is in the works, this will only frustrate Midwestern
  customers. (We ordered ours through a dealer on the other coast.)

  The high frequency 1040 noise reported in an earlier message is
  NOT from the floppy disk drive. It is caused by the switching
  power supply. I'm going to find some way to damp the sound as
  it is driving me CRAZY! I am particularly sensitive to high
  frequency sounds [audiophile comments to /dev/null :-)] and
  some of our machines are worse than others.

  I've been living with a 1040 and 20Mb developer's hard drive.
  This is a SUPER combination with Micro C Shell, microEmacs,
  DEGAS, etc. Can't wait now for OSS Prolog and eventually a
  68020 product (prod, prod....)

FYI (for your information)

>rick@ucbvax.berkeley.edu (Richard R.Sharpe)
>Organization: Rosemount Inc., Minneapolis, MN
>Subject: desktop menu address

>I'm trying to write a desk accessory that can enable/disable itself
>on the desktop menu. If possible, I'd even like to change the text
>on the menu. I've tried to use multiple MENU_REGISTER calls but
>apparently only the first is used.
>Rick Sharpe at Rosemount Inc, Burnsville MN

The menu_register call only installs the desktop applications name when the

system boots up, or when the resolution is changed. To locate the desktop menu, I would suggest that you look at memory, using SID or a similar dis-assembler that can display memory without disassembling. You can find all sorts of nice places in RAM, including all the menu names, and options under them. I have done this to find the location of the DESKTOP.INF files which is kept in memory by TOS. I do not know the exact locations off hand, but you will be able to recognize them immediately.
If your program has its own menu bar, you can place your names/titles in strings, point to the strings, and change the string pointer, or actually change the text within the string. But as far as changing GEM desktop menu bars, this can not be done with sytem calls, you must hack it out.
I have fooled around with installing an icon onto the desktop from SID, and have had success putting additional drives, windows, and trashcans there.
These things can not be done through system calls, since the desktop is 'proprietary' and nothing about its location, or altering it are documented.

Hello,
   In reply to Moews, let me clear up a little here. Every terminal
talks to other computer/mainframes/terminals in ASCII. If not, you
would not be able to to them. Then some nifty programmer came up
with the idea of EMULATIONS. A certain sequence of control or escape
characters that allow the host machine to send to the terminal so
it can tell it to clearscreen/home/position-curson and other such
nifty things. Well, since there are so many programmers out there,
and computer companies. Everyone sort of came up with their own
emulation. VT100 follows ANSI emulation which is Digital's favorite.
IBM has their own too. But it seems that your mainframe, to be nice,
offers several emulations, VT100 being one of them. So, the answer
is yes. Your ST equiped with a decent VT100 emulator should be able
to do the job more than fine. The other emulation is not as popular
so you will have a hard time finding it, I would be most glad that
VT100 came out so soon for the ST, other machines wait years. But,
it should work fine.
                                    Terminaly yours,
                                    Rick Flashman

This is an addition to the message I sent about "Logbase" and
"Physbase". I realize now that the incorrect screen dump may have been a
result of using the GEM desk top screen dump function and not a call
from the current application. If this were the case then it does
indicate a bug. This bug is not in TOS however. The GEM desktop is
itself an application and should set "Logbase" to "Physbase" before
performing the screen dump. "Logbase" should then be restored to its
original value after the dump. You can avoid this problem by making sure
that your application sets "Logbase" to "Physbase" when it is done
updating the screen.

John

I too would like to see a list of the escape sequences for the ST's VT52
emulator (aka ST52). It may not be exactly a VT52, but it may have a lot
of advantages over a straight VT52 after all (color graphics?!).
I might mention that I found out about these escape sequences accidentily.
I log on to a Unix VAX that has an imperfect command completion shell. Once
in a while, when I hit the Esc key to get command completion, I also have my
background/foreground/cursor colors change. The only way I can fix it is
to reboot. Anybody else had this or similar problems?

The Abacus Atari ST Internals book lists the following codes:

```
ESC A -  Cursor UP
ESC B -  Cursor Down
ESC C -  Cursor Right
ESC D - Cursor Left
ESC E -  Clear/Home
ESC H -  Cursor Home
ESC I -  Reverse Line Feed
ESC J -  Clear to End of Screen
ESC K -  Clear to End of Line
ESC L -  Insert Line (really H19 - not implemented on VT52)
ESC M -  Delete Line          "              "
ESC Y -  Direct Cursor Addressing

I'm not sure which of the following are from the VT52, which are from the H19
and which are out of the blue...

ESC b -  Select Character Color
ESC c -  Select Background Color
ESC d - Clear Screen to Cursor position
ESC e -  Enable Cursor
ESC f -  Disable Cursor
ESC j - Save cursor position
ESC k -  Restore Cursor Position
ESC l -  Clear Line
ESC o - Clear Line to Cursor position
ESC p - Set Reverse Video Mode
ESC q -  Reset Reverse Video Mode
ESC v - Enable Auto Line Feed (power up default - opposite of VT52!)
ESC w -  Disable Auto Line Feed

The following are not mentioned, and don't seem to work, but are standard
VT52 fare:

ESC F -  Select Graphics Character Set (for line drawing, etc)
ESC G - Select Ascii Character Set
ESC = - Select Keypad Applications mode (keypad sends escape sequences)
ESC > -  Select Ascii Keypad Mode
ESC [ - Enable Hold Screen Mode (a turkey for sure...)
ESC / - Disable Hold Screen Mode
ESC Z - Identify Terminal Type
..... -  A few others for printer control (pretty rare option on VT52's)

-------------------------------------------------------------------------

As has been pointed out before, there is no emulation of the arrow keys and
functions keys on the VT52 keypad, keypad applications mode isn't implemented,
and the default setting of Auto Line feed is backwards.  Since this code
has been burned into the ROM's, it isn't likely to be corrected.

If you want more complete terminal emulation, you will have to get one of
the third party terminal emulators.  Since the keyboard is derived from the
DEC VT220 layout, a VT100 emulator shoud have fewer strange key mappings.
```

Somebody just posted a rumor about a cartridge providing BLIT terminal
emulation - now that *would* be fun - maybe there's a tie-in to the story
about AT&T buying ST's for use as terminals... Anybody got any facts?

Unfortunately AT&T does not sell the BLIT. They sell the 5620.
The BLIT had a 68000, the 5620 for political reasons has an AT&T custom
processor chip. (It's probably more expensive for them to build it
than to buy the 68000 from Motorola for $10.)

The ST cartridge in question makes the ST emulate a BLIT. In fact,
once a few changes have been made to the BLIT sources, it can run
the same binaries that a BLIT runs. (The changes make things like
the screen size a parameter rather than hardwired in.) All the BLITs
in the world are inside Bell Labs and a few universities.

I guess this might benefit people inside Bell but it's useless to the
rest of us, unless AT&T releases BLIT (not 5620) software to everybody.
Hmm, AT&T could probably sell the 520ST cartridge and the BLIT source code
as a package deal...

Here are the ST's VT-52 (ok, ST52) emulator escapes. Feel free to
give it to anybody.

```
ESC A    cursor up, no effect at top of screen
ESC B    cursor down, no effect at bottom of screen
ESC C    cursor forward, no effect in rightmost column
ESC D    cursor backward, no effect in leftmost column
ESC E    clear screen, home cursor
ESC H    home cursor
ESC I    reverse line-feed (reverse scroll at top of screen)
ESC J    erase to end of screen
ESC K    erase to end of line
ESC L    insert line (current line moves down, cursor positioned at
       beginning of new, blank line)
ESC M    delete line (add blank line at bottom, place
       cursor at beginning of line)
ESC Y    address cursor by <row> <column> biased by 0x20
       (ESC Y 0x20 0x21 is same as ESC H ESC C)
ESC b    set foreground color (lower 4 bits of next character specify
       the color number assigned to the foreground)
ESC c    similarly, for background color
ESC d    erase from beginning of screen to cursor (inclusive)
ESC e    enable cursor (make it visible)
ESC f    disable cursor (make it invisible)
ESC j    save cursor position
ESC k    restore cursor position; if no previous corresponding
       save was made, then home the cursor
ESC l    erase entire line, move cursor to first column of it
ESC o    erase from beginning of line to cursor position, inclusive
ESC p    enter reverse-video mode (foreground <---> background mode)
ESC q    exit reverse-video mode (foreground = foreground again)
ESC v    enable wrap at end of line (auto-LF)
ESC w    disable wrap at end of line
```

("You should have done it THIS way" flames to /dev/null, please).

The RAM controller will NOT handle 2 Meg using 256K chips. To try to
modify the system to do that looks quite hairy to me. On the other
hand, the Byte article stated that your could upgrate the 1040
to 4 Meg when the 1 Meg chips become affordable - just replace
the 256K chips and add an address line. The RAM controller will
handle that. It appears to me that you can to exactly the same
trick with a 520 - there is room on the board, and you would
just piggy back the same way as with the 1 Meg upgrade.

Yes the clones go over the mark (perhaps).. but total rewrites of software
with the same functionality don't. Here's why:

The example given about Star Wars superficially holds water, until you make
the fundamental distinction between Star Wars and (say) Visicalc:

Star Wars is a work of art, and any duplication is both a duplication of
material and of "functionality", as it were. Visicalc "duplicates" such as
Supercalc is only a duplication of functionality. Much like building a better
mouse trap. Copyright (in my LAYMAN'S understanding) only applies if you
steal paragraphs from books, and so on. If you express the same thought better,
(or worse) nobody can touch you.

Copyright suit are only successful if the plaintiff can prove that you stole
his idea. Merely looking the same is not good enough grounds. Nor should it be.

This is my second request for help!
When using a joystick in my second joystick port (the one not used
for the mouse), the system at times believes that keys on the keyboard
are being depressed. This renders the port useless for games that
have keyboard control as joystick movements are misinterpreted as
keypushes.

This can be duplicated by placing a joystick in port 2 and rapidly moving
it in random directions. You will here keyclicks echoed from the monitor.
Is this caused by the keyboard controller IC on the keyboard?

This problem affects many computers. It is not just my machine!!
The local repair shop can only suggest replacing the WHOLE keyboard
for a price estimated between 50 and 100 dollars plus labor.

Summary: THANKS Landon !

We where very happy to receive Landon's conversion utility from Atari binaries to Amiga binaries, since we were dying to get as good a local development environment on our Amiga as the Atari people allready have for quite a while ! Our experiences with the conversion of major ST packages is described below :

We received Landons package with a 3 day delay (on the 4'th of April). It took us some time to get the uuencoded version to work, but after a day or 2 we found it sufficiently reliable for our purpose : to get TOS converted to the Amiga.
We used the 11/20/85 release (the Atari ROM release of TOS), and converted it to a slightly larger objectfile on the Amiga, which took about 1 hour (!). The first tests of TOS seemed to work reliable, though file I/O was slower than expected. Encouraged by this succes, we proceeded on converting the hard-disk driver (version 0.11, the most recent European release).

At first glance the combination seemed to be working allright, however once we started using TOS on harddisk for serious development, we found the following unexplainable problems :

+ The system dies horribly if we visit more than some 10 nodes in our directory hierarchy. It complains about not enough memory, though we still seem to have 700 k available. We cannot do any filecopy (e.g. from RAMdisk to harddisk) anymore.
+ hard disk reading is VERY fast, however we have to still do all our compiles on a RAMdisk since writing on a more than 30 % utilised harddisk becomes slower than writing on a floppy.

Landon, I hope these problems with your conversion utility will be solved soon.
  Gert Slavenburg -:)

If you look into a public domain program with SID you might sometimes
find a copyright entry of DRI or other companies. This doesn't always
imply that this software is a black copy. Keep in mind that the
librarys of the development kit for instance got also copyright entries.
So if you write software under C you'll find a DRI copyright somewhere.
I just tell this, because I stumbled over such things when looking
into new bought software. Feel free to add your opinions.

In the Message from 16 Apr 86 15:45 Keith Nemitz writes:
(excerpt, Keith's replys headed by '>>>', NO FLAMING)
.....
Let's look at the ST features:

>1. Standard 3 1/2" 80 track drives (you can also use 5 1/4" drives)
>   360K single side, 720K double side.
>   >>>your DS can't read your SS.

Sorry Keith, but the ST CAN read SS with DS drive. I do it regularly.
You can even read other formats, if you change the controler registers.

>2. Standard Parallel port that uses IBM printer cables.
>   >>>my friend tried to use his $700 IBM color printer with it and faied.

Don't know what he did. It should work. I know somebody who did it.

>3. Standard RS232 port that uses any modem
>   >>>fine (I have 2 serial ports up to 1meg-bit transfer rate).

Sorry RS232 is a STANDARD. There is a newer standard if you want higher baudrates (RS443?). With your non standard 1meg-bit you can not go farther then 1-2 meters (more?). With RS232 probably 50-200 meters.

>4. Choice of Color or Mono
>   >>>your color screen is incompatable with your mono screen.

Ok, here you got a point. But does the Mac use 640 x 400 with color?

>5. Midi interface
>   >>>nice feature since you can't used digitized sound like mac.

The Midi interface is NOT meant to make music. It is meant to program /control syntesizers etc. That's is a much more sophisticated job then programming dumb soundchips. Modern bands can not live without Midi.

This is not flaming. I won't argue about which computer is better. I like my ST+ (european version comes with 1mbyte) even I think that some features could be added (e.g. bus extension). Keith likes to work with his Mac, because he likes the features of the Mac. So what? We should rather look for a way to transfer software from the Mac to the ST and vice versa then to argue about which is the better computer. Anyway, in 10 years people will laugh about the ST and the Mac.

I am the one who is copying three/four disks of ST software for people who request it. The delay, due to my waiting for Bradley's FORTHMACS, is now over. Disks have been mailed today to Bell (of ATT), Franklin, Bovet, Katz, Mestel. Europeans should now send $3.25 for postage (I underestimated the amount earlier). Some people have been sending too much postage. I am holding that money waiting for instructions: those people may decide to send

some more disks (in which case I will use the cash for postage) or they may direct me to send it back. (All who have sent me disks are invited to send at least one more for FORTHMACS and/or special requests for utilities.)

Just in: an 82 track, 10 sector per track formater. Works great. You get 410K diskspace (SS) (but double sided accomodated too) and otherwise notice no difference (that I have detected). It will be added to the three disks I send out.

From now on, so I won't have to type a long sentence introducing myself as the one who is copying software, I will refer to the software as the Starter Kit.

A product called STKEY allows user programmability of the ST function keys.
It runs as an accessory, and will run with most other programs that
leave start-up accesories intact.

The following program will give a rudimentary introduction to the ST's
MIDI capabilities. I pulled this from the net a couple of months ago.

Richard E. Sansom
TRW Electronics & Defense Sector
{...decvax,ucbvax,ihnp4}!trwrb!trwrba!sansom

```
/* mr.c */
/* Nigel Roles 1986 */

#include "osbind.h"

#define MIDI 3
#define CON 2
#define GM (Bconin(MIDI)&0xff)

struct event {
     int delay;
     char cmd[3];
};

struct event *buffer;

int empty=1;
long bc;
long memsize;
long bmax;

long hz200()
{
     register long save_ssp=Super(0L);
     register long uhz200= *(long *)0x4ba;
```

```
     Super(save_ssp);
     return uhz200;
}

record()
{
     register struct event *bp;
     long now,then;
     printf("Recording (any key to stop):\n");
     while (Bconstat(MIDI))
          Bconin(MIDI);
     then=0;
     bp=buffer;
     bc=0;
     for (;;) {
          if (Bconstat(CON)) {
               Bconin(CON);
               bp->delay= -1;
               bc++;
               break;
          }
          if (Bconstat(MIDI)) {
               int b=GM;
               if (b==0xfe)
                    continue; /* Ignore active sensing */
               if (b==0x90) {
                    now=hz200();
                    if (then==0)
                         bp->delay=0;
                    else

~~~~~~~~~~~~~~~~~~\ lineater,\~~~~~~

awww john, such snobbery ! ;-) kermit has a major advantage over
xmodem for those of us who wander thru bbs's from mainframes, the
connect mode which allows us to login into other systems and set up
the xfer, you just can't do that in xmodem. if someone has a version
of tip modified to use xmodem i'd sure like a copy.

The current "minimums" for a "real computer" seem to be a full travel qwerty keyboard, 80 column by 25 line display (640/400 graphics preferred), 400K non-volitile storage, and 1/2 to 1 meg volitile storage for ram disks, and general program usage. Many would also include a hard disk in their "minimums" list as well. Getting all of that into a single "box" that is both light-weight, and compact, is no easy chore.

Actually, the 1040 *almost* qualifies. The biggest problem is getting some form of high resolution display that won't make you squint like crazy, for a price that isn't rediculously high.

Currently, there are 4 approaches:

LCD's are almost high enough resolution, but a 640x400 mono display can be very expensive, and requires some extra driver electronics. Back lighting has been found to improve immunity to glare, but still, a fairly dark room is reccomended :-).

Flat plasma displays are light and easy to carry, but again, they are not cheap. They are also a little power hungry for battery use.

You could use a "squint screen" such as a 4" b/w tv/monitor. There are a few available for reasonable prices (DAC has some for about $50), but unless you are fond of getting your nose about 12" from the screen (ideal viewing distance is 3xwidth of screen), the fatigue can get quite uncomfortable. I suppose you could mount it on a small tripod :-).

Last option would be a "viewfinder" such as those used on VCR cameras. In this case, there are two problems, one being the ability to "mount" the device near the eye (a "helmet" has been suggested :-). The second

is the eye fatigue of having the finder on one eye for several hours at a time.

There is a market for a "lap computer", or more acurately a "coat pocket computer", which can have the keyboard, monitor, and drive "plugged in", but as the price of computers goes down, especially to the level where the individual rather than the company can make the "home" purchase, the trend seems to be to "communicate instead of commute" the computers.

When you stop to think about it, the bulkiest, and most expensive parts of the computer are not the CPU/RAM but the peripherals. The keyboard, monitor, disk drive, and mouse are the expensive and bulky parts of the package, the "main board" of the ST could fit in a coat pocket (let alone your back-pack).

There are "compromise systems" with features such as "chicklet keyboards", extra small displays, limited memory, slow mass storage. These are acceptable to a small market of "traveling salesmen" type people who just want to "dial in" for some quick figures, but not for heavy, regular use.

Two novel keyboard approaches have also been used. In one case, a dvorak layout makes a "chicklet keyboard" 8"x3" very useful. In another case a "one handed" keyboard unit was squashed into something about 4"x5"x2". Notes taken "in the field" could be downloaded via RS-232 or modem lines. It also had a 5x1 character diplay. At $500, it was an "expensive toy", at $50 (what it would cost to make today), it might be a "useful tool".

One alternative to mass storage is very high speed communications. Perhaps when "digital lines" become more readily available, portable computers will use a "host" as the "disk drive".

As to the original question, "will Atari make a 'lap-top'?", I don't suppose they will. The possibility of someone makeing an electronic notepad which can "feed" the Atari? The probability is very good.

In the long term, my guess is that Atari will drop the direct floppy and printer interface, expand the DMA interface to full SCSI, and run the one cable out of the "keyboard/console" box. One rumor has it that the TT (Thirtytwo Thirtytwo) will connect to the ST, which will work as a "Very Intellegent Terminal/Workstation" as well as a stand-alone computer.

This may help (if you don't soldering): The TV modulator takes as inputs the
composite video signal and the audio signal. If you can figure out which is
which (e.g. by trying both), you may be able to get a picture on your monitor
by just bringing this signal out. However, the level may be wrong so you may
get less contrast than you want. If so, you may have to add some
amplification or pick the signal off at a better spot.

Good luck and hope it turns out to be simple.

> John

You COMPLETELY missed the point of the question. I KNOW how logbase
and physbase work. My program uses them and the result is that I get
nice crisp screen transitions despite the fact that the program needs
several seconds to prepare the next image. OK, now back to the question.

Let me clarify, I did not issue a system call to print the screen. The
manual says that I can hit ALT/HELP (or whatever the key combo is as per
the documentation) to get hardcopy OF THE SCREEN. I hit ALT/HELP and
DID NOT GET HARD COPY OF THE SCREEN. I got hard copy of the image that
was partially built. Had I issued the call, you can be sure that I would
have had the pointers pointing at what I wanted them to point at.

I AM suggesting that the ALT/HELP routine use physbase instead of logbase.
I suppose this implies that the screen dump system should take a parameter
indicating the area of memory to be printed, while the parameter passed in
the case of the ALT/HELP key be physbase.

he use of a the keyboard to get screen dumps is to take care of the
case where the program does not have the capability or desire to provide
the function itself. Instead, it printed the confusing half-built
image that the program was preparing.

I am trying to point out to ATARI that the capability could be made to
operate in a more useful fashion.
Perhaps someone from ATARI would care to comment.

I have an pre-production Atari 20 Mb hard drive, and am now starting to encounter problems. The documentation says to be careful not to copy too many files at once (no limit suggested), and to not have more than about 40 subdirectories across all drives. This slightly worried me. When I created my 20th yesterday, I could not run any application, let alone copy files. The former generated the error "couldn't find application", and the latter "not enough memory to run that application". These I reckon are wide of the mark, as GEM is not expecting the underlying operating system to fold up, so guesses. When I tried to copy files using the command interpreter, I got two bombs (bus error), but the interpreter survived to accept another command. When I removed the 20th directory, everything worked again. Conclusion - GEMDOS is broken. According to show info, I have only 1 Meg of the disk used. According to show (using command.tos), I have used about 4Meg, which is more believable. Without subdirectories, I couldn't find my way about more than about 1 Meg anyway. I need subdirectories. I might also mention that this problem has been rumbling away, because about 3 directory creations ago, the ISV assembler stopped working. It either couldn't find the irritating AS68SYMB.DAT, or created as many temporary files as it could before running out of directory entries.....

Arrggghhh. Thinks - "this is ludicrous - I wish I had time to write my own operating system, which doesn't pale at the the task of handling directories." First year students who've just learnt about operating systems might also be wondering what's so difficult.

My system is a 1 meg upgraded 520st with OS roms, 1 floppy, and one hard drive.

Why has this happened at 20 and not 40 subdirectories?
Why is 40 a limitation anyway?
Is this a known problem?
Have I really got to have huge directories?
Any suggestions?

Please!

Subject: Re: 5620 (blit) cartridge for the ST

    Yes, Dave Galloway and myself have ported the original 68000 Blit software to the 520st. The software, for the most part, is the same as that in the Blit's commercial successor, the 5620. For those of you unfamiliar with the Blit software, this gives you a multi-tasking multi-window smart terminal interface to Unix similar to the facilities offered on the Sun workstation (plus and minus some features).
[For those interested in more details about the Blit, see Rob Pike's article in the April 1983 issue of the ACM Transactions on Graphics, or the SIGGRAPH 83 conference proceedings].

    It was our hope to be able to use these converted atari's as cheap terminals at the university. While the software was quite successfully ported*, the project was somewhat of a failure for two reasons. The most important is that the st keyboard is terrible (ATARI ARE YOU LISTENING?). The second reason is that the screen is a bit small, particularly for multi-window use (although it still beats the hell out of a dumb ascii terminal). On the other hand, I must give credit to atari for the 70hz non-interlaced b/w screen, it is beautiful compared to the 30hz interlaced green screen on the Blit and 5620!

    Anyway, we have a half dozen of these terminals in use by people at the university (mostly me) under BSD 4.2 (impatiently waiting for 4.3 and its accompanying OS window support) and we will live with them until somebody comes out with some better hardware (or we build it ourselves). Unfortunately, all of the software was derived from proprietary Bell software so we are not allowed to distribute it to anybody unless you are appropriately licensed :-(.

*
In conclusion, for those of you already possessing Blit or 5620 software interested in trying to get our software, I must also point out that it is not just a matter of getting the ROMs. We have modified most of the Blit terminal programs to remove the machine dependencies making them binary compatible across both the atari and Blit (except for the main terminal multiplexor). Therefore a complete 10 Meg (or so) distribution would be necessary.
              :-(... :-(

R.T. Bradstrum

This is true: Dave Galloway at the U of Toronto Computer Science
Research Centre is the person to talk to. I saw a demo of the
BLIT emulation: the ST was hooked up to a VAX system by a 9600
baud line and was running a number of windows in a multiplexed
manner. It looked like a small SUN worksation, very smooth.
The snag in marketing this thing is that AT&T would have to licence
it, since it was a port of existing software. The original BLIT
was $10,000 (!) so don't get your hopes up.

Summary: correction to New England dealers assertion...

In article <2610@mit-hermes.ARPA>, jpexg@mit-hermes.ARPA (John Purbrick) writes:
>
> ..... Apparently the owner of The Bit Bucket in
> Newton, Mass., which claims to be the only dealer in New England, is friendly
> with Mr Tramiel, so they get reasonable supplies.

According to people I know who have worked for Jack Tramiel at Commodore, the
owner may have the impression that he is friendly with Tramiel, but Tramiel
in all likelihood does not share the illusion.

Also, in four visits to The Bit Bucket I found their people to be conceited and
more interested in talking about how good they are than in demonstrating how
good they are. I finally found an incredibly helpful operation located in
Framingham, Mass. called CompuClub (617-879-5232 or 1-800-MY-ATARI) - the
owner is Tom Graziano, he has been around for a while, and I have found the
staff to be very knowledgeable and willing to help. Hours are 11AM - 7PM
Eastern.

Prices are also MUCH better than Bit Bucket's, and as of today they had
a half-dozen 1040's in stock waiting to be adopted.

1040 STf's are in stock in Germany in department stores as well as

at Atari dealers - at the same price (I understand the 'f' stands for

the integrated floppy - ?). But believe it or not, they are

delivered without TOS in ROM, although the documentation has been

changed as to omit all references to the 'system disk'. My dealer

says the ROMs will be available about this week.

In the March '86 Question and Answer Bulletin from Atari there was the
following question:

Are there any variables around so I can get the position of the cursor?

The answer stated that the cursor position was kept in a couple of words
at negative offsets from the line A variables base address. Specifically
it said that the cursor x position was at -14 words and the cursor y position
was at -13 words from the line A base address. Well I tried this and
those two words didn't change no matter how much I moved the mouse.
Has anybody else had any success using these two magic memory locations?
Or could somebody tell me the correct procedure to go thru to get the
current mouse position (without using VDI). I know I could intercept the
mouse packets from the keyboard but I would rather not do that if I don't
have to.

Interestingly enough, one of the "undocumented features" on the new STs
that have the modulator built in is that pin 2 (two) is composite
video out. The documentation says its Reserved. You can pick up
the ground from either Pin 8 or 13. The problem of course is getting
hold of the connector. If you noticed that the pins (or rather the
holes) are at 0.1" spacing. I took a perf board with 0.1 centers and
stuck wirewrap pins in them, and it fit beautifully into the video
post. You may try molex pins instead that are rounded, but i did'nt
have them handy.

I sincerely hope Gert is joking. There are these nasty little things called
copywrite laws, often used to protect developers of software which Gert
himself professes to be. I hope Atari isn't foolish enough to encourage
wholesale piracy of their software with their own tools.

Summary: U.S. laws have changed, International laws haven't.

In article <294@hope.UUCP> corwin@hope.UUCP (John Kempf) writes:
>> I just couldn't let that one go by. "Not public domain in the United States"?
>> Supposed I get a public domain copy in Germany and bring it here?
>> Does it cease to be public domain?
>> --
>Hong Kong does not honor US copyright laws,...

International copyright agreements, and copyright laws of most countries
are patterned after the 1919 copyright laws. The U.S. passed a revised
act in 1978 which improved protection of Broadcast, music, film, video,
and software. Prior laws covered little more than works in "human readable
form". Current laws cover almost anything that "can be captured long enough
to be reproduced".

If the copyright was registered in the United States, it would be protected
here, no matter how you got it. If the copyright notice was removed in Germany
(because it's "public domain") and the software showed up in the U.S.,
you might be able to plead ignorance, but I doubt it would help.

if so,
I'll wait until next week).

Please respond via mail if possible, I don't always have lots of time
to peruse this group (though I'll try just in case it was too much trouble
to mail).

In article <755@minster.UUCP>, nigel@minster.UUCP (nigel) writes:

> I have an pre-production Atari 20 Mb hard drive, and am now starting
> to encounter problems.

Aha! Please contact Richard Frick or John Feagans, at Atari, or
Robert Katz, at Atari in Britain, for a new hard disk driver. You
need it. Right now.

> First year students who've just learnt about operating systems might
> also be wondering what's so difficult.

Tee hee. Talk to DRI.... :-)

> Why has this happened at 20 and not 40 subdirectories?

The number is small and arbitrary. 20 is about the limit -- actually,
I suggest 16 or so. This covers *all* directories on the hard disk.

> Why is 40 a limitation anyway?

The DOS that DRI wrote uses a form of static allocation. It
permanently allocates structures that describe the disk hierarchy; if
you have a lot of directories, GEMDOS runs out of memory -- with
potentially disasterous results.

> Is this a known problem?

Yes. The production 20-Megabyte hard disk driver will alleviate the
problem somewhat. Atari is working on a more permanent solution
(actually, a couple different ones).

> Have I really got to have huge directories?

Yup. 16 of them, until you get the new driver. Then it's 40 or 50.

> Please!

You're welcome. (You think we /like/ this kind of problem?)

Subject: ST Calendar Desk Accessory (SOURCE)
Message-ID: <210@atari.UUcp>
Date: Thu, 24-Apr-86 15:19:24 EDT
Article-I.D.: atari.210
Posted: Thu Apr 24 15:19:24 1986
Date-Received: Sun, 27-Apr-86 06:32:48 EDT
Organization: Atari Corp., Sunnyvale, CA
Lines: 547
Keywords: ST Accessory

Here is a shar file containing the source for a simple "sort of
perpetual" calendar desk accessory.

```
#! /bin/sh
# This is a shell archive, meaning:
# 1. Remove everything above the #! /bin/sh line.
# 2. Save the resulting text in a file.
# 3. Execute the file with /bin/sh (not csh) to create the files:
#    cal.c string.c
echo x cal.c
sed 's/^X//' > cal.c << 'xEOF'
X/*
X * cal.c -- simple TOS desktop calendar accessory
X *
X *  provides a "perpetual" (well, really 1980-2009) calendar page display
X *  uses vertical scroll bar:  arrows move by month, shaded area by year
X *
X *  link68 cal.68k=accstart,cal,string,osbind,vdibind,aesbind
X *  relmod cal
X *  ren cal.prg cal.acc (must be DESKN.ACC in early TOS)
X *
X *  - a further experiment into the realm of writing a desk accessory
X *  This was a personal experiment to learn more about desk accessories.
X *  It may be freely distributed, on an "as-is" basis.  Comments and
```

```
X *  suggestions are welcome.  This is NOT an official, supported,
X *  Atari product.

The advantage may be this: the BLIT was a 68K-based bitmap tube built
for Bell Labs internal use. The Teletype 5620, the commercially
available unit, is NOT a 68K-based system (WE32000?). So the BLIT
support software may be seen as having so little commercial value that
AT&T may well license it for some reasonable fee. Anyone at Guilford
Center listening? (please?)

    What timers are available for the user? In particular, to use with
the MIDI ACIA. I would like to get a little finer resolution than 200Hz.

>
>Try to be a little patient and I'm sure a machine will turn up for you.

    Another possible explanation is that Atari is REALLY screwed up!
    I have been selling 520STs locally since last October, and naturally was eager to sell the 1040 when it was anounced. I spent the first two months trying to get my distributor to sell me one - the answer was always just wait a bit longer. Finally Neil@Atari gave me the name of another distributor, since Atari had changed their distribution channels and the old distributor got cut off.
    The new distributor said fine, send your money. Two weeks later I hadn't heard ANYTHING, and called them. They said to call Atari. Atari said that there was a packet of paperwork to file to become a 1040 dealer. Naturally no one had the time to tell ME that, even though I had ordered several thousand dollars worth of machines.
    Another week went by while I waited for the application they were going to send the next day. I sent it back and waited a couple days before calling them since I had been told it would just take one day to approve the application and then the hold on my order could be released.
    I have called Atari 12 times between 8 April and 22 April and every time the story was 'we are evaluating the applications this morning call back this afternoon', or 'we didn't get to it today, but you can get our answer if you call back tomorrow afternoon', or 'she is in a meeting, give me your number and she will call you back (guess if she ever did!)', or 'he is out of town today, call back on Friday.'
    In summary after having Atari pull arbitrary switches on me that I wasn't told about, after filling out their paperwork, after sending them thousands of dollars at the beginning of March, after repeatedly being lied to by them on the telephone, I ended up still not knowing if they would CONSIDER sending me 1040STs, let alone having them send me any! I pulled the plug and have asked for the money back, let someone else have the headache! A company that treats dealers as badly as Atari does will be in big trouble financially even if they have a decent product.
    Now I wonder how long it will take them to get their act together and return my cash so I can look for a product which I can actually GET, and thus have a real chance to make money on?
    As for Atari, well they lose out on the half dozen individuals that wanted their equipment and the two companies that wanted to place multiple unit orders with me. But I would rather pass on that business than ruin my reputation by repeating to others the untruths that Atari was feeding me about how long things would take. They aparently don't operate in a world of deadlines, or else they assume that their customers don't. Bad assumption.

Aha! Please contact Richard Frick or John Feagans, at Atari, or
Robert Katz, at Atari in Britain, for a new hard disk driver. You
need it. Right now.

> First year students who've just learnt about operating systems might
> also be wondering what's so difficult.

Tee hee. Talk to DRI.... :-)

> Why has this happened at 20 and not 40 subdirectories?

The number is small and arbitrary. 20 is about the limit -- actually,
I suggest 16 or so. This covers *all* directories on the hard disk.

> Why is 40 a limitation anyway?

The DOS that DRI wrote uses a form of static allocation. It
permanently allocates structures that describe the disk hierarchy; if
you have a lot of directories, GEMDOS runs out of memory -- with

potentially disasterous results.

> Is this a known problem?

Yes. The production 20-Megabyte hard disk driver will alleviate the
problem somewhat. Atari is working on a more permanent solution
(actually, a couple different ones).

> Have I really got to have huge directories?

Yup. 16 of them, until you get the new driver. Then it's 40 or 50.

> Please!

You're welcome. (You think we /like/ this kind of problem?)

The problem is one of memory, your version of AHDI doesn't allocate enough
memory for more than twenty subdirectories. A new version of AHDI has been
available for a few months that solves this problem, contact ATARI-UK for
a copy. If they don't have it, its available on the ATARIDEV section of
compuserve, but you need to be an authorized developer to download it
                  This should do it

> As far as we can see 1040's will not support tv! Only monitors.

The store that sold me mine said different--that the rf modulator and
composite generators would arrive later and be fitted at no charge
"in a couple of months". I've checked pin 2 (composite monitor) of
the monitor plug and as far as I can tell without opening the case,
nothing is wired to it. I hope they'll sell a cable with the 13-pin
monitor plug at one end and 2 RCA plugs at the other for audio and video.

Sometimes when I first turn my 520ST on, after one or two seconds
the screen goes blank (i.e. black) for just a moment. It looks like
the power is turned off for just an instant. Then the boot-up procedes
normally.

I have the 520ST. I installed the OS roms a couple of weeks ago. I have a
monocrome monitor. If anyone knows anything about this problem, I'd
appreciate knowing about it!

Eric Bergman-Terrell (CSNET address: terrell@ohio-state)

There is a new version of the hard disk driver (ahdi.prg) that is in the
auto folder, which relieves some of these problems. It may be downloaded
from CompuServe (ataridev) or your favorite BBS. If you have any problem
getting a hold of it, i can mail you a uuencoded version.

    Another possible explanation is that Atari is REALLY screwed up!
    I have been selling 520STs locally since last October, and naturally was eager to sell the 1040 when it was anounced. I spent the first two months trying to get my distributor to sell me one - the answer was always just wait a bit longer. Finally Neil@Atari gave me the name of another distributor, since Atari had changed their distribution channels and the old distributor got cut off.
    The new distributor said fine, send your money. Two weeks later I hadn't heard ANYTHING, and called them. They said to call Atari. Atari said that there was a packet of paperwork to file to become a 1040 dealer. Naturally no one had the time to tell ME that, even though I had ordered several thousand dollars worth of machines.
    Another week went by while I waited for the application they were going to send the next day. I sent it back and waited a couple days before calling them since I had been told it would just take one day to approve the application and then the hold on my order could be released.
    I have called Atari 12 times between 8 April and 22 April and every time the story was 'we are evaluating the applications this morning call back this afternoon', or 'we didn't get to it today, but you can get our answer if you call back tomorrow afternoon', or 'she is in a meeting, give me your number and she will call you back (guess if she ever did!)', or 'he is out of town today, call back on Friday.'
    In summary after having Atari pull arbitrary switches on me that I wasn't told about, after filling out their paperwork, after sending them thousands of dollars at the beginning of March, after repeatedly being lied to by them on the telephone, I ended up still not knowing if they would CONSIDER sending me 1040STs, let alone having them send me any! I pulled the plug and have asked for the money back, let someone else have the headache! A company that treats dealers as badly as Atari does will be in big trouble financially even if they have a decent product.
    Now I wonder how long it will take them to get their act together and return my cash so I can look for a product which I can actually GET, and thus have a real chance to make money on?
    As for Atari, well they lose out on the half dozen individuals that wanted their equipment and the two companies that wanted to place multiple unit orders with me. But I would rather pass on that business than ruin my reputation by repeating to others the untruths that Atari was feeding me about how long things would take. They aparently don't operate in a world of deadlines, or else they assume that their customers don't. Bad assumption.

> As far as we can see 1040's will not support tv! Only monitors.

The store that sold me mine said different--that the rf modulator and
composite generators would arrive later and be fitted at no charge
"in a couple of months". I've checked pin 2 (composite monitor) of
the monitor plug and as far as I can tell without opening the case,
nothing is wired to it. I hope they'll sell a cable with the 13-pin
monitor plug at one end and 2 RCA plugs at the other for audio and video.

There is a new version of the hard disk driver (ahdi.prg) that is in the
auto folder, which relieves some of these problems. It may be downloaded
from CompuServe (ataridev) or your favorite BBS. If you have any problem
getting a hold of it, i can mail you a uuencoded version.

If there weren't so many people like you, it would be easy to get 1040ST's!
What I mean by that is there is such an AMAZING demand for them that we can't

nearly supply them fast enough.

This is an example of what's known in the business world as a "high class problem".

Try to be a little patient and I'm sure a machine will turn up for you.

Price: $799 list.
Capacity: 20 megabytes
Speed (transfer rate): 7.5 megabits/second
Availability: sometime in May, probably late in the month. And probably will be in short supply for the first while, like any new hardware product that EVERYONE wants.

I went back and tried the Intersect RAM Disk, and it does work - as long as I don't have Mike's Ramdisk on disk at boot-up. This is not too surprising since each is going to try some initialization when loaded, but I thought I tried dropping Mike's Ramdisk before when it didn't work with TOS in ROM. That combination did seem to work with TOS.IMG in RAM, though. I now use the ramdisk from Landon Dyer at Atari, which doesn't suck up accessory slots and installs itself.

Something else I noticed was that the first demo in the Abacus GEM Reference fails for me if I have the BICALC.ACC Desk calculator on disk at boot-up. This is a pain, because I like the calculator. I have to wonder why accessories fight so much with each other and with applications.

A fellow I met yesterday is moving to Italy in about a month. He has a 520 ST he bought here in Vancouver, and is wondering about the best course to take. He has a stock 520ST, a single-sided drive, a color monitor, and a Panasonic 1092 printer. What will 50Hz power from a step-down transformer do to the power bricks on the computer and drive? Will the colour monitor get upset? Will the printer get upset? Seems to me that it should all like 50Hz power, but sometimes things get warm, and sometimes they die. If there is anyone with any practical experience out there, advice would be appreciated. Please send mail; I will summarize to the net if there is any interest.

numeric pad that it has and the VT-220 style that the ST has is that the cursor keys are located in the positions of the *, -, +, and Enter key on the numeric pad. The enter key itself is split into two smaller keys.

---

11 New On Compuserve.....4

---

1. Corrections

In the March 1986 issue I mis-stated a description of the real VT-52 keyboard. This device actually does have a numeric pad and cursor keys. The difference between the your new and bigger buffer. Be sure to restore things when you exit your program for the benefit of the application that follows yours.

---

3. DOS

*

Q: How do I get the address of the DTA buffer for use with the Fsfirst() command?

A: There are two ways that you can do this: 1) Allocate a buffer yourself and use the Fsetdta(ptr) to tell the system about it, or 2) ptr=Fgetdta to use the one already defined.

*

Q: I am running out of stack space when I link with apstart.o. Where do I edit to increase the size?

2. BIOS

*

Q: How do I make the buffer larger for communication over the MIDI port?

A: Use the xbios call Iorec(MIDI) to get the address of a structure which contains a pointer to the existing buffer. Change it to point to

Question and Answer Bulletin

A: You need to construct a mono-plane mask with zeros where the image in memory will be transparent and ones where the image in memory will occupy space. Use the copy raster transparent (vrt_cpyfm) with transparent mode to cut a hole into the screen. Second use vro_cpyfm with "or" mode 7 to move the color image to the screen. See section 6 of the VDI manual for further details.

---

5. AES

*

Q: How do I hide and show the mouse?

A: Use the graf_mouse call. A useful thing to include in a header file are the following definitions:

```
#define HIDE_MOUSE
```

A: Look for the label ustk in apstart.s. Directly preceding it you will find a statement ".ds.l 256". This statement allocates 256 * 4 words, or about 1k of stack. To increase the stack to 8k, make it ".ds.l 2048". Remember that declaring local arrays in C will eat more stack space--allocate accordingly. To make the apstart.o you must assemble your new source by as68 -l -u apstart.s.

---

4. VDI

*

Q: How do I transfer a color image from memory to the screen without copying the background around the image?

```
        graf_mouse(256,0x0L)

  #define SHOW_MOUSE
        graf_mouse(257,0x0L)
```

*

Q: In the mentst.c example program, why are so many parameters in the evnt_multi call zeroed out?

A: The reason for this is that in this example program we are only interested in returning if there was mouse event. We are not interested in keyboard, timer, or button events, hence we have a dummy pointer as place holders in those parameter positions of the evnt_multi.

---

6. Desktop

*

Q: How does the AUTO folder work?

A: If you create a folder named AUTO, the system looks for it on power-up boot and will execute any programs it finds inside. If there is more than one program, the programs will be executed in the order that they were created in the folder. These programs are named *.prg but

7. Accessories

---

8. BASIC

*

Q: The accountants in my 50 million dollar company do not like my basic programs as large numbers will end up with a few pennies added to the end. What can I do?

A: You are seeing the effect of a single precision

it is not possible to have an auto-starting GEM application. However, the programs may use the VDI, DOS, and BIOS. A good example to try is to place STWriter inside an AUTO folder and it will start running on power-up. When you exit STWriter, initialization resumes and execution brings up the desktop. AUTO folders are generally used for drivers such as those for the hard-disk and printers.

Q: How can you get the name of the data file that initiated a program with an installed document type?

A: For programs that have undergone the install application option at the desktop, it is easy to get the name of the document. The desktop program places the file name string in the command tail. The command tail starts 80 hex into the base page. You can get this information by accessing the base page directly, or by main(argv,argc) from a C program that uses gemstart.o.

---

scientific math package. The maximum number of significant digits that can be stored is 6 to 7. Decimal fractions cannot be accurately represented by a binary floating point structure. To overcome the latter limitation, you can store all numbers as pennies, only inserting the decimal point when inputting or outputting them. To gain extra significant digits you can save each number as an integer whole and fractional part. To really gain significant digits you might consider writing some math routines which operate and store numbers in strings.

---

9. LOGO

*

Q: I keep getting an edit buffer full error. I have tried turning off buffered graphics and not loading desk accessories to get more space. Will getting ROMs help me?

A: The edit buffer is a fixed size. You need to break up your program into smaller

segments and load them in. Getting the ROMs would only give you more program storage and would not increase the

option specifies the drive on which temporary files are created. The variable d: is the drive designation. For

size of the edit buffer.

---

10. Development Tools

*

Q: How do I get the C-Compiler to make a listing of my program with line numbers

A: The Alcyon C currently supplied in the developers kit does not have an option for generating a listing. Errors that are reported can be found by using the editor to step to that line in your source. I hope that someone out there will write a print/header and line number generating program to share with us in the data libraries in the developers SIG.

*

Q: I am including stdio.h and linking with gemlib and libf, but I still have undefined symbols etoa and ftoa in the link step when I use printf.

A: The order of the library files in the link are important. Make sure that libf is listed after gemlib. If you have any doubts you can also list it as libf gemlib libf.

*

Q: I have a RAM disk program. I would like to speed up my links by putting all the linker created temporary files on the RAM disk. How do I command the linker to do this?

A: For LO68, -F d: The -F LINK68 TEM[d:].

---

Hong Kong does not honor US copyright laws, so just about anything published
there has stamped on it 'not for import to the US' or something similar.
this may be a similar case.

Subject: problem with C modulo operator using Developers Kit
Message-ID: <402@oscvax.UUCP>
Date: Tue, 15-Apr-86 19:48:18 EST

Article-I.D.: oscvax.402
Posted: Tue Apr 15 19:48:18 1986

Lines: 30

There is a problem in the Atari Developer's Kit when using the
C modulo operator (%) when both operands are longs. The problem
appears in the following way. Consider this short program,

```
#include <stdio.h>

main()
{
    long i;

    for ( i = 0; i < 10; i++ )
     printf( "i = %ld, i %% 3 = %ld\n", i, i % 3L );
}
```

If you compile this and link it with gemlib it will work as expected.
However if you link it with vdibind and gemlib (as you would in a
program that uses VDI routines) in that order, the result of the i % 3L
operation is garbage. We traced it down to the fact that both vdibind
and gemlib contain the lrem function which is used when finding the
modulo of two longs. Evidently the one in vdibind is buggy whereas the
one in gemlib works. Therefore when we linked with vdibind before
gemlib the buggy version was linked in. It seems to me that vdibind
shouldn't even contain this routine (it also contains lmul.o and
ldiv.o). These routines should be (and are) in the C runtime library
(gemlib). We just took them out of vdibind and everything works OK now.
Is there some reason these routines were in vdibind?

> produce unique or distinguishible codes. Has anyone else noticed this?

The ST keyboard outputs "scan codes" which are numbers that identify the key that was depressed but which bear no relation to ASCII. The keyboard handling code in TOS has some translation tables which map the scan codes into ASCII characters.

The trouble is, the default translation tables translate all the special keys, including the arrow keys, into the same ASCII code which happens to be NULL (ASCII code 0). Unless a program explicitly requests to change these translation tables, it gets the same ASCII code for each of these special keys.

I suspect that the VT52 emulator just uses the default tables. It is somewhat of a pain to try to look at the scan codes for the special keys and map them into something sensible. The definition of "sensible" is also somewhat difficult in the context of a VT52 emulation (VT52's don't have arrow keys, so what ASCII sequence do you transmit for these keys?). They should have emulated a VT100 or something a little more modern instead. On the other hand, the VT52 command set is somewhat less baroque than the VT100's.

The keyboard code in TOS is pretty screwed up in general. Here is one gotcha with changing the translation tables: If you change them, you must make a system call to put back the default ones before you exit, otherwise the system will lock up (because you have presumably put the new tables in your program's address space, which TOS clears to all zeroes when a program exits). So far, no problem. Your program should be careful to restore the translation tables. But what if TOS kills your program without giving it a chance to fix up the keyboard? Here's how this can happen: If your program is not presently asking to read the keyboard, and you happen to type a control C, TOS will kill your process. If a conin() request is pending when you type the ^C, your program gets to see the ^C and handle it itself. If no conin() is pending, the program gets killed.

Does anybody know how to get control of the ^C handling? I would like to find some way to prevent my program from getting killed without giving it a chance to clean up. (It doesn't seem possible to keep a conin() request pending all the time, because, for instance, when you are in the middle of a long write() to a file you are sensitive to being killed). Clearly one should just not type ^C, but I would like to make my software "idiot proof".

Mitch

Have talked to Atari at the Hannover fair and to my dealer, and
they told me..

> If they are not released yet, when will they be?
> If they are released, how much do they cost, how much do they
> hold, HOW FAST ARE THEY, and where can I get one?

for Germany: the hard disk (~20 MB) will be delivered in June
(his year, i hope :-)), it will cost ~2000 DM (~830 US$). I have
been told that the drive is very fast, but I couldn't check it
myself.

> Any information at all would be great! Also, how about other
> companies' ST hard disks? Any good ones? Is there a tape backup system
> for the ST? (There are lots for the IBM & IBM mutations)

I have seen some at Hannover. There were drives from ~20MB up to
~80MB, pricing from ~2300DM to ~4500 DM, but I can't remember
the company.

Not quite true, they have shown a prototype of a MSDOS-Emulator
(not PCDOS). It comes with an 8MHz 808[86], 512KB ram (useable
as RAM-Disk from TOS) and MSDOS 2.11 (not sure about this).

The emulator should be ready for delivery fall '86.

Hi there ---
   A relatively short time back, a kind and gentle person implied that he/she would be posting a printer condiguration file for the PANASONIC series printers that can be used with "1st Word." Where is this driver, and can I have a copy? (I have looked in net.sources for it, but, alas, it was not to be found....)
  Thanks in advance....

{(*/* Pure-E-net Line (eater) Chow */*)}

Hello!

For my undergraduate thesis, I'm doing work in the area of speech recognition (isolated word). In order to do the high speed data acquisition and analysis that is needed, I was thinking of putting a TMS320 series signal processor, and some other support chips on the high-speed DMA port on the ST. Now, I don't have any hardware documentation for the ST, other than a book published by Abacus Software called "ST Internals". Unfortunately, this book has only one page on the DMA interface which does not have much meat in it. However, it does say the following:

> "Since most of the external devices will use a Controller IC, the signal CS, Chip Select on pin9, must also be available. The signal A1 is also to be seen in connection with this, because it is then important if the controller has more than one register. This signal can distinguish between two registers."

This seems (to me) to imply that the DMA port can address only two registers. Is this true, or are they missing something (am I missing something?)?. I found this surprising because a while ago, from a SASI/SCSI discussion on this net (net.micro.atari) there was talk about this port being able to address 256 external devices or something like that. How?

Would somebody please shed some light on this? Has anyone done any interfacing with this port, could they please tell us what their experiences were like, any pitfalls etc. I'm sure there are others on the net who are interested in this as well, so email or post to the net. Also, if there is sufficient interest in this, I'll summarize the replies I get via email.

Thank you for your time,

Anees Munshi

Summary: Mac or Mac+

In article <1315@unc.unc.UUCP> hultquis@unc.UUCP (Jeffrey P. Hultquist) writes:
>
>   Is there some way to convince a 1040 to read a MacIntosh disk,
>   and vice-versa?

On the regular Macs, which use the "Incredible Woz Machine" drive,
the chances are very slim, each ten or so tracks, the density changes.
This was originally done to improve reliability on inner tracks and
improve density on outer tracks. Appearantly, the Mac Plus drives
are a little more "conventional" and may be easier to use under some
sort of standard interchange mode. You might be able to hack up the
Mac OS to write ST format disks.

The best way to get bytes between the two machines is to use a
serial link or modem and kermit or xmodem. Perhaps, when Atari
comes out with their SCSI interface, you will be able to transfer
disks between those drives. Other problems such as directory

formats, "resource" (file) formats, and meanings of data would
have to be handled via software. It probably wouldn't be too
hard to write a program that enables the mac to read ST disks.
Going the other way might not be so easy.

Hope that helps a little.

In a prior message I said that the reason our VT52 emulator does not support

the numeric keypad and the cursor keys was that a VT52 doesn't have such keys.

Our own engineers quickly pointed me to the VT52 in our office, where, big as life, the keys can be found.

My only defense is to remove the offending keycaps, but they restrained me.

In a 1040 brochure, I picked up the other day, they mention the SH 324.
This is a hard disk, 20 MB formatted, with controller, interface, and
power supply in one box. Connection with the ST is through the DMA interface.

On another page, they say something about a data transfer rate of 1.33 MB/sec
However, I've not yet seen this thing in a shop.

I've heard that the Haba disk is indeed available around here. A price of
fl. 3000,-- was mentioned, so it should be available in the US somewhere
around 1000 dollar.

Help folks. I bought my ST recently for the purpose of driving my MIDI keyboards. Being a Computer Engineer, I decided to roll my own instead of paying for the commercial programs. However after tearing through the documentation, I don;t see anything that describes the MIDI interface.

I.E. How do I get data to and from the MIDI ports? Does anybody have any C code that does this??? I would like to get something that works already, however I would be glad to get just the address of the ports and the transition rules that apply to them. If anybody has pointers to any documentation, please include that also. I have a tight schedule in writing this stuff since I want to get it working for my Ensonic first (VES for 399$) Hah! I'll write my own.

Thanx in advance...

Peter Barada

I just read on att.blit that the University of Toronto has developed
and is currently using a 5620(blit) terminal emulator in a ROM
cartridge for the 520ST (mono). Does anyone know if this is true?
If this is cartridge exists I would like to buy one and I'm sure a
lot of other people would too. Can anybody out there confirm or deny
this??? I think a product like this would be a great boost to ST
sales, I hope it makes it to the market place.

I have worked with real honest to gott vt52 terminals and they do have a keypad.
In fact, the best editor for RSTS (Really Silly Timesharing System) is KED.
KED stands for Keypad Editor for you fortunates who never used this system.

Summary: Object code converter posted to net.amiga

Landon @ Atari just posted an Amiga object code to Atari ST translator.
If you have any friends with Amigas, and you've seen binary for it
that you cant get for the Atari (yet), this little utility might help.

Again, thanks Landon.
Any chance of getting something to go the other way?

HELP! i am trying to compile microemacs 3.5 and i am having no end
of trouble, basic.c dies in c168 with "early termination of link
file", bind.c dies simularly. I am running a 512k 520 with tos in
rom, the compiler (alcyon) is on the a: disk and the program is the
only thing on the b: disk. is anyone out there having any sucess ???

I don't quite follow your line of questioning, so I will just throw this out
and see if it helps:

GEM was written for the PC. Atari had this new machine (the 520) and liked
the GEM environment, and asked us to provide such an environment on the 68k.
Original plans were for some sort of crude DOS emulator on top of CPM/68K.
But one of our (former) engineers, Jason (born to code) Loveman had a "Dos
Jr." prototype running (this is the infamous JasonDos written about in
Inforworld (I think)). It was a better alternative to bring this prototype
to production than coerce CPM/68K to do the same, so GEMDOS was born. It
was developed under CPM/68K, and so the Alcyon compiler was used. So:

GEMDOS uses the Alcyon compiler, and I presume Atari does too (we hand code
over to them for their mods); thus the familiar object format. It is not, nor

has it ever been CPM/68K.

I read in a recent posting about The Club that there were escape codes you could send to the built-in VT52 emulator to get graphics on the ST. I already figured out the foreground/background codes, but are there more? The poster said he'd started referring to the emulator as an ST52. Can anybody post a list of escape codes on the ST52? If this is included with the Developer's Kit, could somebody like Landon Dyer post it, so we know it's not proprietary?

By the way, I called the number given for The Club II, and got a human who knew nothing about it. The number I called was (313) 334-8877. Did I get it wrong?

Thanks all..

Why do you think?

The load file format for TOS programs is identical to that for CP/M-68K
programs, except that the relocation information has been compressed.

The header at the beginning is the same because the load files are at least
that similar.

Let's get our stories straight, Karl. I think he was referring to the load
format, which is essentially the same.

Certain memory locations, for example the data and address registers and
user and supervisor stacks, do not get erased when the rest button is hit.
Therefore, one can reboot after a crash and those locations will have
precisely the numbers they contained at the point the crash occurred. The
mushroom analyzer simply displays the contents of each of those locations.

You can get a mushroom analyzer by sending a blank floppy disk, SASE and
packing material to

> ^C, but I would like to make my software "idiot proof".

You CAN catch ^C (as well as any other terminate). In the grand DRI
tradition, it is the usual monster kludge:

---------------- (excerpt)

     0x102 Terminate (^C) Handler
               Before a process is actually terminated, GEMDOS
          calls the terminate vector. If the terminate vector
          points to an RTS (the default case), the process will
          be terminated. If the application does not wish to be
          terminated it should do a longjump (or its equivalent)
          to an appropriate handler.

This is extended vector 0x102, located at 0x408 in protected RAM.

The vector is called on ANY terminate (including function 0x00, Pterm0()).
It also catches the "mushroom" exceptions (bus errors, etc.). In actual
practice, about all you can do after a bus error is to clean up any
hanging data structures (vblank handlers, keyboard tables, RS232
buffers, etc.), RTS, and hope for the best.

One of the things you have to restore is the vector itself ....

^C is only checked for on cooked console input OR output. So if you
use purely BIOS calls, or just GEMDOS file I/O, you are safe. Also, raw
input from the console ignores ^C.

When I had this problem it was simply shorted address lines. With the upgrade
the screen memory ends up in high memory, thus the wierd display. I located
the address lines in question by using SID to write to a large zero filled
array one byte at a time and observing which locations caused more than one
location to change.

If you are unlucky the shorted lines will have to be located visually because
you won't be able to keep the system up long enough.

Keywords: cheaper? better?

I read an article in this newsgroup suggesting that it was cheaper by
~$200 to upgrade a 520 to 1Meg than to buy a 1040. My question is,
is there any reason to buy a 1040? Aren't there some advantages to
the layout, or ports, or something that make the price difference
worthwhile? Or should I just laugh all the way to the bank (heh)
and get a 520?

Your expert comments appreciated...

I had a similar problem with ^Q/^S when I wrote a terminal emulator
-- sometimes they would be passed through to my program and sometimes
they would be interpreted by TOS. My advice from Atari was to avoid
the GEMDOS conin()/conout() calls altogether and to use the BIOS
calls directly. I did that and the problem went away. But even
though the problem was only with keyboard input, it seemed to be
necessary to avoid conout() as well, for it interacts in mysterious
ways with conin().

There are 3 reasons that I would rather have a 1040ST:

1) It comes with a double sided disk drive instead of a single sided one
2) There aren't nearly as many cables to deal with. This is more of a
   hassle than you might think.
3) It already has the 1 Meg of RAM in it. This means that I wouldn't have
   to hassle with the upgrade and any chance that I might screw something up.

By the way, I have a 520ST that I upgraded with 1 Meg. I am not
at all sorry that I bought it when I did, but if I were buying an Atari today
I would get a 1040 for the reasons given above.

> ..!ihnp4!ihopa!riccb!djb

Don't hunt for it visually at first -- that takes forever and may never
find the short. Instead, use a modern digital VOM (Volt-Ohm-Meter),
preferably one with a "beeper" continuity check feature,
to measure between each address line and all the others.
Takes only a few minutes.
     Once you've found the guilty pair, then go visual, or
even rip those two out and re-do them.
Don't use an old non-electronic VOM, as they may feed
high enough currents thru your chips to damage them.
Also make sure your instrument won't indicate continuity (short)
thru forward-biased solid state junctions (as in chips), thus
giving false short indications. Test it on a diode, both directions,
to be sure.
     If you can't borrow such a VOM, Radio Shack sells them
for $40 (sale price, tho). Worth every cent if you hack hardware.
     Best of luck, mike k

The following is what I found somewhere as a termcap entry for the ST. Is
this correct (or does somebody have something better)? This isn't (yet)
in our local termcap file, and the standard vt52 entry doesn't seem to work
quite right.

```
A5|520st|atari|atari 520st vt52 emulation:\

I've wondered about that too. Some advantages of
the 1040 may be:

(1) Peace of mind knowing that the extra RAM is factory
installed, and if it breaks Atari will (?) fix it.
I upgraded my RS CoCo years ago (from 16K to 64K, wow)
but must accept the fact that Radio Shack will never repair
it. If you're not a hardware jock like me, get the 1040.

(2) Doesn't the 1040 come with a built-in (less desk space)
double-sided drive? That's worth about $75 I believe.

(3) Can you still daisy-chain two external disk drives?
If so, the 1040 could have total of 3 drives, not 2.
 (I doubt you can, tho).

(4) Built-n power supply. Actually, one may prefer the
separate black-box to the bigger, heavier, and HOTTER
mainframe that results from putting the PS inside.
Especially since the keyboard is still not separate.
So, maybe this is a *disadvantage*.

(5) If you piggyback a 1040, you can put in 32 chips
and go clear to 2 Meg. Don't ask whether the MMU chip
can handle that much. In case you missed the Byte 1040ST
article, the "extra" RAM chips are end-to-end with the "original"
ones on the board. You could add just 512K the first time.

(6) How long will you live with 512K? If you plan to upgrade
a 520 as soon as you get home (and blow the warranty),
maybe you should get the 1040 right off (see (1)).

     mike k

A computer dealer made a good point in favor of the 1040: The "keyboard"
unit on the 1040 contains a power supply, disk drive, and TV interface.
So if you want to travel with your computer, you only need to take the
keyboard and connect it to any handy TV, and you're in business!

I have just received Bradley's FORTHMACS which is the first real release (shareware) of the PDFORTH that I posted to the net some time ago. You may recall that I have offered to copy three disks worth of software for anyone sending me three floppies. I have now added a fourth disk containing FORTHMACS. You may still send me three disks if you do not want FORTHMACS or send me the fourth disk for FORTHMACS. Or you may send one disk for the FORTH. Or you may send me no disks and download all the files from GENIE (wait about 5 days before looking there-it will take awhile to upload. I will not try to upload to compuserve as it will take into the next century to do so). Or you may write directly to the author, Mitch Bradley (see the address below). I strongly recommend that you do the latter since Mitch will then know who you are and can keep in touch.

However, if you are going to send me three disks then, in my opinion, you should send four disks: FORTHMACS is fast (a few hundred times faster than xlisp) and has hooks into everything. The following is a list of files that come with FORTHMACS and illustrates what I am talking about:

File	Contents
FILES.LST	This file
READ.ME	General Forthmacs information
COPYING	Important note from the author
FORTH.TOS	The Forthmacs Forth System
EMACS.TOS	The Emacs text editor
EMACS.REF	Emacs quick reference
TUTORIAL.TXT	Emacs tutorial

BUNDLE.FTH	Creates "bundles" -- files containing many other files
EXTRACT.FTH	Used by BUNDLE.FTH
INTERVAL.FTH	Interval timing

```
SPLIT.FTH     Split-screen scrolling
BLOCK.FTH     Implemention of the Forth word BLOCK
BLOCKIO.FTH        Used by BLOCK.FTH
BLOCKLD.FTH        Used by BLOCK.FTH
COMPARE.FTH        File comparison
CHECKSUM.FTH       File checksum
DEBUG.FTH     Single-steping debugger
WHATIS.IND         Index file for the WHATIS help command
WHATIS.DOC         Data file for the WHATIS help command
INDEX.FTH     Recreates WHATIS.IND if you modify WHATIS.DOC
FILEDATE.FTH       Modifies the data and time stamp on files
MEMORY.MAP         Text file showing the memory map of Forthmacs
```

You don't have to keep all these files on-line all the time for Forthmacs to work. Once FORTH.TOS has started, it stays in memory until you exit from Forth. The first time you type edit , EMACS.TOS is read in to memory, and it stays there until you exit from Forth. WHATIS.IND and WHATIS.DOC are accessed every time you use the whatis command, so you have to keep them on-line if you use that command. The other files are only accessed if you explicitly ask for them.

You can also get FORTHMACS from the author at the following address:

Bradley FORTHWARE
P.O. Box 4444
Mountain View, CA 94040

Note: I just mailed disks to the following people: Hauser,Franceus,Dalio, Carson,Jaegermann,Gerard. I had delayed your disks for a few days waiting for the FORTH (I had to squeeze everything to get it on - sorry).

John Franco
2535 Spicewood Lane
Bloomington, IN 47401

Keywords: Infringing ROM Copyrights
Xref: watmath net.legal:3295 net.micro.atari16:507
Summary: Can Apple stop people from doing this?

What is a line eater?

A company has developed some software and a cartridge for the
Atari ST computer that allows Apple Macintosh roms to run on the
Atari ST. They take official Apple roms and plug them into their
cartridge and then their software lets the ST run Macintosh software.
I spoke with the developer who wonders if Apple will/can stop them
from doing this. It seems that when people have their dealers upgrade
the roms, the dealers keep the old roms. You can (or could until
this situation developed) then buy these older roms.

I hope that net.legal is the proper place for this discussion (it has
been on net.micro.atari16). Some of the questions are:
1. Is there any copyright infringement? I believe there is none, but
    the developer thought Apple might so claim.
2. Can Apple suddenly claim the roms as proprietary? The roms are
    evidently availble (officially) for somthing like US$195.
3. If Apple tries to restrict this product wouldn't they expose
    themselves to restraint of trade claims?

I am not in any way involved with this product and only find the situation
exceedinly interesting. I think the idea is great and that Apple shouldn't
be able to stop it (but then with our legal system the way it is, they might
force the developer to stop by consuming mass quantities of money fighting
Apple's lawyers).

About a month ago, bammi@cwruecmp.UUCP (Jwahar R. Bammi) posted some
GEM documentation titled "ProGEM part 1 of 6". I found it quite
interesting, but this site never received parts 2-6. Were they ever
posted, and if so, could some kind person please mail them to me?

-Thanks

Here is the 1st Word printer driver for the Panasonic printers. I'd sent this out before but apparently it did not get out to everyone. The following is in two parts, the documentation for the driver and the hex file itself. To use it just perform the normal install proceedure as described in the 1st Word manual. Since I didn't write this, and haven't used it all I can't take responsibility. Good Luck. /bill

----------kxp1091.doc----------

This 1ST_WORD printer driver is compatible with the following printers : PANASONIC (1090,1080,1091,1092,1592 1093. As well as these ROLAND (1010,1011,1111). Since the light function is not available on these printers, I have substituted for proportional mode.

Here are a list of changes and additions :

LIGHT mode (F4) is now set for Proportional mode

In the special character menu on the second line there ten characters which for lack of a better term I will call LCD characters, like a calculator display's. Since only the Atari printer is capable of reproducing these I use them to enact special funtions like :

LCD (0) NOW used to turn ON ELITE pitch printing
LCD (1) NOW used to turn OFF ELITE pitch printing

LCD (2) NOW used to turn ON CONDENSED printing
LCD (3) NOW used to turn OFF CONDENSED printing

LCD (4) NOW used to turn ON ENLARGED printing
LCD (5) NOW used to turn OFF ENLARGED printing

LCD (6) NOW used to turn ON DOUBLE space printing
LCD (7) NOW used to trun OFF DOUBLE space printing

LCD (8) NOW used to turn ON 1 1/2 space printing
LCD (9) NOW used to turn OFF 1 1/2 space printing

OPERATING NOTES:

1: It is impossible to print both in ELITE mode and NLQ
   at the same time.

2: When using the double space feature place the LCD 6
   before the line where you want duoble spacing to
   begin. And place the LCD 7 where you want it to end.

For example if you want "The lazy dog" to be double spaced :

ON S C R E E N	ON P R I N T E R
Mary had a little 6	Mary had a little
The lazy dog 7	
	The lazy dog

*
* Translation Table
* =================
*
* This table provides translation from single Atari input bytes into
* multiple Epson printer codes, and is useful for printing extraneous
* characters such as accented characters etc. All characters are
* subjected to translation, but if there is no entry in the table for
* a particular code, then the original code is sent to the printer.
*
* The entries must be arranged in ascending order of Atari input
* code. The table is NULL terminated.
*

I've had my 1040 just over a week, and I'm pleased. It was worth waiting a
couple of weeks, as I had to do. Apparently the owner of The Bit Bucket in
Newton, Mass., which claims to be the only dealer in New England, is friendly
```

with Mr Tramiel, so they get reasonable supplies. In fact The Great Jack favored the store with a visit last week--he could hardly do that if the shelves had been empty.

A Bug. The composite and r/f outputs aren't installed. I called the store when I discovered this, which is important to me as I have a b&w system and it's my only way to see color; in fact Neo won't run at all in monochrome. They said the modulators will arrive in a couple of months and then they'd install them free. Grrr.

I recently received my new 520 ST. It's great. I've got TOS in ROM and the connector for output to my T.V. I own an old medium res color monitor which I would like to use with my ST. The monitor wants composite input. I recall reading in this newsgroup several weeks ago that composite output would be available in the new ST's, however there doesn't seem to be any obvious way to get a composite signal out of my machine.

I noticed in the pinout for the monitor connection that one pin is for "General Purpose" output. Is this a composite signal? Do I need a special cable? Does anyone out there understand how to get a composite signal?

Thanks for your help,
John Cadley

>on the actual screen

>Have I found a bug? Is there any way to fix it?

No. You haven't found a bug. If you think about the reasoning behind having two locations "logbase" and "physbase" you will see that it is working properly. The ideas is to allow the programmer to perform page flipping while using the system routines for writing to the screen. In order for this to work you must display one screen but have the system routines use another. Thus, there are two pointer, one points to the memory which is to be displayed on the screen (physbase) the other to the memory which is to be used by the system routines (logbase). If you want the system routines to work on the currently displayed memeory then you must set "logbase" to "physbase". If you started having system routine use physbase then you would loose flexability (Printing one screen while viewing another for example). To solve your problem simply set "logbase" to "physbase" before calling the screen dump routine and restore it after you return.

This is a question directed to anyone with a 1040 system. The Byte interview
in the March issue mentions a possible graphics coprocessor as well as an
integral rf modulator for the 1040 system. According to my local dealer
(Personal Computers of Ithaca) the 1040 does not and will not have the
rf modulator and the graphics coprocessor will not appear in later versions
of the 1040. It wil be used instead in the next generation machine. He
cited his dealer's newsletter as a source. Is this in fact the case?
The rf modulator might then make the 520 a more appealing purchase. Does
anybody know anything about this?

Summary: MacCartridge and Apple

In article <2093@uwmacc.UUCP>, demillo@uwmacc.UUCP (Rob DeMillo @ Madison
Academic Computer Center) writes:
> A question about MacCartridge:
>
>   Did I miss something? Why should *anyone* care about Apple's approval?

> If the thing was made *wothout* any Apple software or hardware, what
> legal claim do they have to prevent this fellow from selling them?

     As I understand it, MacCartridge is designed to use the Macintosh ROMs.
This *is* use of Apple's software, and so needs to be approved by Apple, unless
you can get their ROMs through another source.

> Apple tried to stop distribution of GEMDOS, and they lost...and they
> should have, look-alikes and compatable components are *not* copyright
> infrigements...at least not the last time I looked....

     Again, from what I've heard, some changes *did* have to be made to
GEMDOS as a result of an out-of-court settlement between DRI and Apple. The
current precedents in U.S. law indicate that copying of the "look and feel"
of software *is* a copyright infringement.

~~~~~~~~~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~~~~~

i can't be done, the code was never put into the vt52 emulator, i
recommend PC/INTERCOMM VERY highly, its well work the money and does
everything i need done for communications/vt100 emulation

>dash of pepper?
~~~~~~~~~~~~~~~~~~~~~~~~~~

I work with both the (512K) Mac(at work) and a (1Meg) 520ST (at home)
...there is no comparison in my mind...the ST is 'better' for ME...
(obviously not because it has more software [since it doesn't] -
as you must be trying to point out)...nevertheless even the ST software is
coming along...most Mac developers appear to be porting their software
over...and a number of third party developers are developing software for the
ST that is and may not be available to the Mac.

Ever try doing data flow diagrams with MacDraw...forget it...tho' i have
done them fairly easily on the ST with EasyDraw...(MacDraw forgot why anyone
would want an arc to have an arrow at the end)

..."better" is such a curious word...does a machine with no color option,
bizarre communications architecture and limited expansion mean better???
I, of course, do not imply that that the Mac is without virtues. Apple
had a corner on the market a few years ago...but their are other machines
with equal and superior hardware characteristics today. If 'better' is
only software then the Mac is also quickly losing that edge and check
back in a three or four months (i think the Mac software edge will be
zip).

Thomas-

Return your ST immediately! There seems to be a hardware problem.

A friend of mine had the same problem. He got a new one. I think this

line shifting is due to a failure of the video counter in the

GLUE (or the MMU? Where was the videocounter?).

In theory yes, but the Atari Monitor uses seperate horizontal and vertical
sync input, while the Amiga outputs a combined sync signal. There are
seperate sync outputs on the RGB connector, but they are for the Genlock
peripheral and are not designed to drive a monitor directly.

If you do not make an adapter with circuitry to buffer the signals, you may
find that your Amiga will not boot...

Hello, I ran across a nasty C compiler bug the other day:

The C source:

```
     struct foo {
          ...
          unsigned array[1]; /* 8 bytes from start of struct */
     };

     func()
     {
          register struct foo    *baz;
          register unsigned  index;

          ... = baz->array[index];
     }
```

generated:

```
     ...
     <move baz into a0>
     <move index into d0>
     swap d0
     clr  d0
     swap d0
     clr  d0       <- no matter what index was, it's now 0!
     mov  8(a0,d0),d0
     ...
```

So beware using register unsigned's as array indices.

Surely you other developers out there have compiled a list of bugs to
avoid...could you please post them to the net to save everyone from hardship?

Forced to read the .s output files,

Jan Gray Looking Glass Software, Waterloo, Ont.   (519) 884-7473

>
> Does anyone know how to predict whether a .prg will execute from AUTO
> with TOS in ROM?

TOS will execute files

     <bootdevice>:\AUTO*.PRG

in the order that they are in in the directory (as opposed to
the order they APPEAR to be in in a desktop window). You cannot
do AES calls from a program in the auto folder.

Usually the boot device is A:, but that can be changed by the
boot sector, if the boot sector so desires. Thus, with the DAS
BOOT ROMs, you could boot from B: (or, if you were extraordinarly
lucky or flush, C:).

This works with any version of TOS, be it in ROM or in RAM.

Does anyone know if there are any quirks in Settime(t)? I passed in a time/date encoded long and the time didn't seem to change. I then dumped the long into binary, and it looked like the correct format. Is there anything else I need to do? (I am doing this from GEM, if this causes a problem)

Also, how does the AUTO directory work? Does it run the first program it finds, or all programs? What about non-executable programs? Do GEM programs run? If I put in a GEM program and a resource file will the program run?

Thanks,

--- Bri

Hello out there (Neil are you listening??)

I have had a 1040 on order at my local computer store for ~3 weeks, and the dealer does'nt know when they are going to arrive.

question 1: Does anyone know why the 1040's are so long in coming? (neil??)

question2: where is a good dealer in the baltimore area.

Peace and longlife,
Paul F.

I had a quick peek at the Atari booth in Hannover the other day.
They were not showing the ms-dos cartridge/emalator yet, which was
rumoured to be there. They said they expected it in june.
Price unknown.

The booth was a small one, with atari giving away brochures, and some
people, supposedly from small companies, showing some stuff on ST's.
I've seen someone playing with habacad, someone playing with musical
apparatus via the MIDI interface, someone with a CCD camera and a printer
connected to the ST, and someone with stuff for industrial automation.

However, no shocking innovations.

I know enough people at InfoCom to feel able reply to this. Yes, they took
a beating on Cornerstone. Supposedly sales have picked up a fair bit since
the price reduction. ActiVision has (so far) not been very intrusive, but
that may change. The best game-writers are still with InfoCom.

Basically, InfoCom's problem was in not saving its pennies. They had a very
bad habit of profliigacy--like renting their expensive new headquarters, just
in time to lay off half the staff and have to let a good bit of it sit empty.
Hacker-entrepreneurs take warning!

Hello,
     Has anyone out there used EASY DRAW on the ST? I played
with it at the dealer's and I liked it ALOT. It's an object
oriented paint program like MacDraw. Since i only used it for

about 15 minutes, I would like to know if anyone has any impressions
of the program after more extensive use. Is it worth the 129.00
my dealer charges for it? If I buy it I'll post a review, but
I'd like to know what I'm getting myself into...

Peace and long life...

Title: ***OS-9 SUMMER!***

The OS-9 68K Atari ST port will be demonstrated at Commmdex.

I have just talked to MicroTRENDS and they will be demonstrating a number of things at this year's Comdex. The big news is that shortly we will have OS-9 available from MicroTRENDS for most of the popular computers. This includes The IBM-PC, the Atari ST, the Amiga, and the Apple II anddd IIe. ALL 68000 based. There's more, but I have to post this stuff in spirts.

==========
os.9/news1 #59, from jimomura, 397 chars, Fri Apr 11 22:47:49 1986
Comment to 58. Comment(s).

MicroTRENDS also announced that they are licenced to market an Deluxe Software. The datafiles for this software will be directly portable with the IBM-PC version. This means direct compatibility between IBM-PC and OS-9 at the application level for people upgrading their IBM-PC's with the multi-user OS-9 68000/68010 cards currently avaiillable.

==========
os.9/news1 #60, from jimomura, 300 chars, Fri Apr 11 22:51:10 1986

Comment to 59.

     MicroTRENDS also announced that they will hold a CDI workshop in conjunction with Microware either at the end of September or the beginning of October. Please note that the fact of the workshop is solid. The date has yet to be finalized. For more details, ccall MicroTRENDS at (312) 310-8928.

Subject: How close to ALCYON C is TOS?
To: info-atari16@su-score.stanford.edu
X-Original-To: info-atari16@su-score.stanford.edu

Quote of the week: "What do you do when the people you knew were the plastic
                    that melted and the chromium too? / Who are the brain
                    police?"
                                                          -frank zappa

I have received a lot of buzzing about an entry I had on the net.

RUMORS was the name. In it I asked if TOS was really cp/m68k. No
it is not everyone said. But I'll bet it's written in ALCYON C
because the file header format and the exception format are too close
for coincidence. I didn't say why I asked at first, but perhaps I should
have. I write a lot of cpm-68k programs, and simply wondered whether the
object format (output from as68) was compatible. DRI claims rights to all
of the cpm-68k development tools, but they are actually third party
products -- i'll bet the same third party products that made cpm-68k, Tos,
and that are distributed in the developer's kit.

THE FOLLOWING IS HEARSAY FROM A TRUSTED SOURCE

David Betz writes about developing xlisp for the Atari using MicroEmacs
under CP/M-68K. This was said to be in the _BYTE_ section of *Compuserve*.
So, has anyone used the crippled cp/m-68k *and* TOS who can explain why
header format is the same and so forth and yet TOS was to have been designed
from the ground up?

-frank zappa

Does anyone out there think Atari will ever develop a lap computer based
on the ST? I would love to have a 68000 computer that would fit in my
backpack. It would be swell if it had something other than an lcd display,
and as far as i'm concerned battery life is not as important as being able
to carry the @#$%~ thing from one office (i.e. home) to another (i.e. !home).
Are there real practical reasons why this cannot be accomplished? The market
in PC lap computer seems pretty active, so there's money to be made. The last
I heard (about 18 months ago) the Packard Goose was promising such a computer,
running un*cs and p*m, within the year. Time passes. . .
What do you ATARIers think?

Have the ST hard disks been officially released yet? I hear bits of information about them, but haven't seen advertisements, etc.

If they are not released yet, when will they be?
If they are released, how much do they cost, how much do they hold, HOW FAST ARE THEY, and where can I get one?

Any information at all would be great! Also, how about other companies' ST hard disks? Any good ones? Is there a tape backup system for the ST? (There are lots for the IBM & IBM mutations)

Thanks,

--- Bri

foo!
Well I did it. I attempted the fatal up grade. The good news is that I
did not fry my ST. She boots-up all right along with the 5 or six
accessories on the desk top [fonts,ramdisk,etc...]. The ramdisk says
~690+K byte available! Looks good right!?

However a little after after boot-up,vertical lines appear up and down
across the whole screen!!! Sometimes the lines shift color as I move the
mouse. I can still run programs, copy files to and from the RAM disk,
but invariably, after a short time it crashes, lines and all. My
thinking is that one of the RAM chips is flakey. WHy?

A. the vertical lines appear on every 8th pixel

B. When pressing memory to its limit by coping whole disks into
the RAM disk, I can see the patterns of these vertical lines
change in exact sequence with the "clicks" of the floppy disk.

Questions: 1. Any suggestions on what else it might be?
2. How does one test for a bad RAM chip?

All comments will be MOST welcome. Thanks - Geoff

By the way, I used the directions found in the April 1986 issue of
Computer Shopper. This upgrade doesn't use the 68 OHM RESISTORS.

In article <8604060607.AA07358@ucbvax.berkeley.edu> CON.REILLY@SU-GSB-HOW.ARPA
(Brian Reilly) writes:
>the MacCartridge might be helpful to those developing this product, but
>how can they be convinced that the $100 or whatever they might make
>on each cartridge isn't just a loss of $2500 for the Mac and peripherals
>that they didn't sell (and Atari did)? It would be great if Apple
>gave the okay and allowed them to market their cartridge, but I don't
>know if there are too many good reasons why Apple would want to do that.
>David Small also said that selling the cartridge without the ROMs was
>not something he would consider.
>
>- Brian Reilly
>-------

May I make a suggestion? There was mention of something to the
effect of getting Apple's approval before the product is marketed.
Mr. Reilly is right? Why would Apple ever want to approve something
that would hinder one of their products?
I believe that David Small should take his product to Digital Research
or Atari directly to market his product. When I saw this, the first thing
that comes to mind is how useful this would make the ST in terms of
taking advantage of available software. And to me, having a machine
of the caliber of an ST being Mac compatible is a helluva lot more
meaningful than an ST being IBM compatible, simply because the Mac and the
ST are much more similar to each other
than either is to an IBM.

I hope he can pull it through! Good luck with this David! My vote
has been cast.

Aloha,

Summary: Yes, Public Domain is Subject to National Boundaries

     John asked if Public Domain status is subject to national boundaries.

The answer is yes. I won't go into all the details, but why on earth wouldn't it be? Sovereignty of nations is one of the cornerstones of international law. Your country certainly can't dictate what is going to be Canadian Law any more than Canada can dictate what will be U.S. law. What one country recognizes as public domain is always a local matter. You can agree to recognize the status as property granted by some other nation, but they certainly can't force it on you.

Cheers! -- Jim O.

Whoops - I forgot to insert INIT.LSP onto one of the three disks I am copying for people. It is so short and the number of people needing it is so long that the only practical way to get it out is over the net. Hopefully this will be the last such transmission.

The file below should be named INIT.LSP:

```
--------------------------cut here----------------------------
; get some more memory
(expand 1)

; some fake definitions for Common Lisp pseudo compatiblity
(setq first  car)
(setq second cadr)
(setq rest   cdr)
```

```
; some more cxr functions
(defun caddr (x) (car (cddr x)))
(defun cadddr (x) (cadr (cddr x)))

; (when test code...) - execute code when test is true
(defmacro when (test &rest code)
          `(cond (,test ,@code)))

; (unless test code...) - execute code unless test is true

Yes..Yes..in fact at a local computer shop (in Seattle) there is an
Amiga hooked up to an Atari Color monitor...the Atari monitor according
to the merchant is much better than the Amiga monitor...i do not know
the details of how or if anything special is needed.

Has anyone seen a problem in which a joystick plugged into the
second joystick port on a 520 ST, can confuse the computer into thinking
keys are pressed?

To simulate this, all I have to do is plug the joystick in the port
and start wiggling the joystick in a random fashion. Sooner or later (usually
sooner) you will hear an audible keyclick. This causes problems
with games that use the second port as these "fake" keyclicks at
times will pause a game or take it to another mode.

Now, who knows how to fix this? My computer is of 7/85 vintage. Maybe
it only affects early computers.

Any information will be appreciated as the local repair people never
heard of this problem.

I got this note from Jim Tittsler which should answer the AUTO question.

From: inuxc!ihnp4!lll-lcc!vecpyr!atari!jwt (Jim Tittsler)
Date: 11 Apr 1986 10:56-PST
Subject: .prgs in \AUTO
To: inuxc!iubugs!iuvax!franco
Message-Id: <513629794/jwt@Beauty>
Status: RO

Well... firstly, whether or not TOS is in ROM should not affect what
      runs. Have you found something to refute that?

Anyway, GEM has not yet been initialized (and the desktop not yet
      built) so programs should avoid doing GEM calls. The display
      driver exists, so VDI and LINEA calls are legal.

AUTO is particularly handy for things that do "Terminate and Stay
      Resident" calls like device drivers (RAMDisks, the hard disk
      driver, the CD-ROM driver, OS hacks, etc.).

All programs in AUTO will be run (at least an attempt will be made)

Summary: How to diagnose/fix a ST memory after imperfect upgrade

Several letters recently have discussed problems with the upper bank of ram
being "available" but not working properly. A few weeks before that,
several letters here have referenced mysteries about the ST not recognizing
new ram after a ram upgrade. One referred to it as due to an intentional
change of the hardware by atari to prevent the upgrades on new ST's.

I have the developers kit (including schematics and listings). I did an
upgrade from inspection of the schematics and at first I had some errors due
to bad solder connections. In the developers kit is a utility called SID,
a debugger, which allows you to look at memory.   With it I determined
that only the lower 1/4 of the new memory was responding, the upper
3/4 was behaving just like memory addresses above 1 Meg (nonexistent memory).
(Since then I have seen situations where none of the upper bank responds).

The dynamic memory controller is reponsible for ram refresh and maybe dtack
generation. It has to be programmed by the CPU for how much memory
is there. The dram controller is initially set at powerup for 4 Meg.
then the machine does a simpleminded memory check on each bank. First it
tries 128k, then 512k, then 2 Meg. After it has sized memory for each bank
it writes a new memory size initialization byte to the memory controller.
It also saves this value in address 424.

When you expand the St memory, if you make one bad solder connection, the
memory check will probably fail and the dram controller will be reinitialized
so as not to refresh or respond to the upper bank at all. So, you won't be
able to troubleshoot it until you reinitialize the memory controller.
But if it is failing the memory test you want to KEEP the OS in low memory.
So first boot the machine, then reinitialize the dram controller by writing
a 5 to the dram controller port at 0xffff8001. SID will buserror, but

when you restart SID you will suddenly be able to access the upper
memory bank.

Now you can diagnose the memory. First, to look for bad data/ras/cas lines on
the new rams, write all ones (0xffff) and all 0's to a location in upper memory
(0x80000 say), read it back, and look for stuck data bits. Visually inspect
and physically try to move the pins on the data in/out & ras/cas lines on
the memory chip which corresponds to the particular data bit. Resolder the pin.

To look for bad (stuck at one) address lines, write a program to zero out all
of upper memory, and then write ones to the first word (0x80000) and have the
program search the upper bank for a nonzero word anywhere but the first word,
and if you find one print its value and address. Again, the nonzero data bit
of the value tells you which chip. The nonzero bits of the address correspond
to address lines of the chip which are stuck at one. Inspect and repair
(resolder) the pin.

To look for bad (stuck at zero) address lines, write a program to zero out all
of upper memory, and then write ones to the last word (0xffffe) and have the
program search the upper bank for a nonzero word anywhere but the last word,
and if you find one print its value and address. Again, the nonzero data bit
of the value tells you which chip. The nonzero bits of the address correspond
to address lines of the chip which are stuck at zero. Inspect and repair
(resolder) the pin.

In all three cases if you make the repairs dictated by a particular diagnostic
and afterwards the diagnostic does the same thing, you should change out
the memory chip.

What's worse is when you made a mistake on the upgrade and the particular
problem is NOT discovered by the boot's simpleminded memory check. It goes
ahead and tries to use upper memory, which is corrupting itself. Therefore it
dies while it is booting. To get around this, pull off ras from the upper
memory and clip the pin high, to force the diagnostic on the high bank to fail.
Boot the machine on the lower bank. Now remove the clip pulling ras high
and clip ras on (while the machine still has power of course). From
this state you can troubleshoot the memory as described above: initialize
the DRAM controller and run the diagnostics.

To those people who have sent me three disks to copy software onto:

  I am delaying sending those disks back to you for a couple of days as
I am expecting some pieces of software which are very much improved over
similar pieces I have now and I intend to substitute them for the older
pieces. Please hang tight (or loose depending on which part of the
country you are in). More details will follow (when I get the stuff).

Wanna know how I get mushrooms? I use the mushroom analyzer! The
first time I exit from the analyzer, I get three bombs (yup, got TOS
in ROM). If I use the mushroom analyzer again, I get two (and I keep
getting two).

I haven't looked at the code, so I don't know what is causing it. I
never noticed this when I had TOS in RAM.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***
It looks like that you certainly have a bad bit. Since the screen
memory is placed in the uppermost 32k of memory, you can see it on the
screen. I would suggest using sed to deposity end retrive bytes from
addresses in the upper 512k range to determine which bit is bad, and
then replace the chip coresponding to that bit.

When the discussion about the lack of
vt52 keypad sequences on the ST first
came up, the Atari reps replied that
there WAS no vt52 keypad. I sent one
of them transcriptions of the appro-
priate pages from the vt-100 & DEC EDT
manuals, explaining both the codes
produced and the physical layout of the
vt52 keypad. I presume they never
have seen a real, live, vt52 (I know
I havn't). I don't know if the Heath-19
(a vt52 workalike, w/ the addition of
an insert/delete line code) has a keypad.
perhaps that is what they were working
from. Anyway.... Atari has had the info
passed to them & are aware that they
left something (well, not really VITAL)
out of their vt52 emulation. Whether
they are going to do something about it
is still unknown. The only reply I
recieved is an acknowledgement of my
message, with no real info about whether
any action would be taken in future
ROMS.

The clones go one step over of the mark ... If I produced a "Star Wars"
movie "clone" with a similar script, plot, names, and ending the courts would
knock it down in a flash -- even though it was "original" work BASED OR NOT
on the real movie.

The clones go WAY OVER the copyright mark by using restraint of trade as the
issue against the "big bully IBM" -- if the PC was produced by a middle
weight company like Altos or Dual they would be struck down in a flash with
copyright infringement based on "derivative works" or outright piracy.

There are dozens of ways to re-write "Return of the Jedi" most would not fly
in the face of a copyright suit .... I don't know why computer jocks are
so dam fire sure they are immune to REAL copyright infringment proceedings.
Rewriting/coding some ones program (bios, application, utility or OS) is
the same is rewriting a movie --- if not legally corrupt, it is clearly morally
corrupt.

Apple doesn't have much say about the manufacture of the cartridge if it doesn't
contain Apple code when shipped .... they have a lot to say about where their
roms go. If there isn't any fine print about License of the code, they can
make service spare roms an inventory item and place a $1,000 charge/credit
on them to insure that the roms are used to replace defectives in the
field.

How far is up?

Why change a perfectly good object code format? You think reinventing the wheel is fun, maybe? Executable file loaders are not hard to write.

The GEMDOS C compiler is the Alcyon C compiler (a couple of centuries old -- ask DRI why they haven't released any new versions in the last couple years) -- the SAME compiler that also runs on CP/M-68K. Only the changes needed to make it run on the ST were made.

The only differences between CP/M-68K and GEMDOS binary files are:

- The relocation information is compressed (say, to about 5% of the total file size, on the average) under GEMDOS. (Those of you familiar with CP/M-68K are nodding your heads right now).

- There are no "absolute" files under GEMDOS (thank God).

You could do ST development under CP/M-68K, if you wanted to. In fact, that's what Atari did in the early days of the project.

Geoffrey- (and others)

That's typical for a faulty RAM bank.

Either one RAM is not ok (number 8 or 16 of the upgrade) or there is

a bad connection somewhere. Check all connections] Next test the RAM's

by interchanging them, e.g. 1 with 8 etc. If the bad lines are now on

different locations you found a bad RAM. If nothing changes try other

combinations. If still nothing happens, there must be a bad connection

somewhere. Please report to me.

A few weeks ago I posted a plea for help about a problem I was having

with my 1 meg upgrade. I won't repeat the lengthy problem description
again but I will describe the solution.
The problem (screen going bonkers when oscilloscope probe touched RAS
connection of upgrade) was eliminated when the 68 ohm resistors were
replaced with 33 ohm resistors.
The only response I received from my plea was from a hardware expert
at Atari Corp. That dispelled any bad thoughts I harbored about
Atari customer support. Thanks Doug.

A true VT52 does not have arrow keys, function keys, or even a numeric
keypad. The Atari emulator follows this guideline.

Go to Macintosh dealers. Tell them you want to buy the ROMs. They'll sell
them to you. But Apple may start requiring dealers to ask for serial numbers,
so you'd have to know someone with a Mac to get them.

> Does anyone know any more about the company which has developed a
> cartridge that plugs into the ST, allowing it to run Macintosh software?
>
> - Brian Reilly
> -------

yes, i just used it at the West Coast Computer Faire, it was done by
David Small and was running MacPaint on the ST when i saw it. David
admitted that there were still some problems with it (minor ones)
and that he had only tried it with three Mac programs. Since it uses
ST drives, it can not run disk protected software since the programs
have to be copied to a ST disk to be run. MacPaint looks so much
nicer on a ST and runs about 20% faster because of the improved
screen access. The bad news is that David feels that he must market
it thru Apple (for legal reasons), if Apple turns him down then he
will drop the whole thing into the trash icon. Perhaps if we all
wrote Apple and told them that we would buy the cartridge then they
might be moved. Hey, i worked for tinkerbell didnt it (:-) ? David
didnt announce a selling price but a good guess would be about
$400-600, (figure cost of roms, dave's profit, Apple's royalities
etc.) I am serious about writing Apple, I think all of Dave's hard
work should be rewarded.

Hello,
     I am in the process of writing a BBS with term program for the ST.
This will be a graphical BBS, which will be GEM oriented, so you will not
be limited to text only. We are going to support communication of the
entire library BIOS, XBIOS, AES, VDI, GEMDOS, the works. The BBS uses a
sliding window protocol for error-free transmission. The term program will
also be able to communicate with normal hosts, probably as a vt100.

     I would like to solicit suggestions for features that you think make a
good BBS and a good term program. Right now the major feature of the term
program will be its macro capability. If there is anything that you would like
to see, please suggest it.

                    Peace and Long Life,
                    Paul Franceus

No, this could not be true. The ST uses its own operating system called
TOS or GEMDOS, depending on whether it's Atari or DRI which tells you.

The CP/M-Z80 emulator is not Public Domain in the United States, and is not
generic enough to be run on any given 68K computer without modification.

Does anyone know of a good Fortran compiler that is available on the Atari ST
NOW? I am trying to port a large graphics program written in Fortran to the
ST. Full access to GEM is not necessary so long as there is some way to get
graphics on the screen (even if I have to read and write raw memory it's ok).

I am looking for a 1st word driver that works with the Panasonic K1092
dot matrix printer in both near-letter-quality and draft mode.
If it is not easy to e-mail it to me, please send me a printout
(I will provide a self-addressed stamped envelope).

Thanks in advance,
...Evangelos

In case you did not go to the West Coast Computer Faire, here is some more
information about the MacCartridge. It was displayed at the faire
by the developers and it looked pretty good. I can't remeber the name
of the company, but I have it on a flyer and will send that along tomorrow.
The two guys who made the thing and wrote the software said they felt there
was a 50-50 chance that Apple would approve of their product and let them
produce it, but I think that is a little too optimistic. They also
said the price would probably be $50 over the cost of the ROMs ($180).
They said it had worked with MacPaint, MacWrite, and Microsoft BASIC, but
that it does not work with FatBits in MacPaint. I don't remember too
much else of what they said, but there was a lot of interest in their
booth.

I'll post the address of the company tomorrow.

Here is a module to interface with the extended BIOS. I took it off
Compuserve and is posted here unmodified. The author's name is Bob
Debula. Also included is a module I wrote to get the arguments in
the command line. It's nothing amazing but handy if you haven't written
one yourself. The program, of course, has to be 'TTP' if invoked from
the desktop.

We have been receiving continuing rejection notics in attempts to
forward mail to the following addresses. All other attempts to
correct the situation have failed, so we are removing them from
the list(s).

If you know any of these, please advise them to contact us about
getting reinserted on the list(s).

I notice that there is still some ierest in upgrading 520's to 1 Meg.
After upgrading mine, I rewrote the document on upgrade, and posted it
to "INFO-ATARI". I don't think it made it to INFO-ATARI16. There was
a *mistake* in the other documentation that I have seen for the 1 Meg
upgrade, and my document corrects that mistake. Besides, my document
is much clearer on the installation of the 68 ohm resistors. I hope
this helps someone.

Joe Augenbraun
augenbra@udel-scrooge.arpa
April 5, 1986

I have just completed the 1 meg memory upgrade on my 520st using a 1 meg upgrade
document taken off of a bulletin board in Florida. I found the document a
little difficult to follow, and there was one major mistake in it. I am not
sure if there are different versions of the document (I think they all derive
from a posting that I saw on INFO-ATARI a while ago). Rather than sending a
correction, I decided to rewrite the whole document. I hope that this will help
those people who have yet to make the upgrade. The document below is derived
from the version of the memory upgrade that includes the 68 ohm resistors (the
one that reportedly was tested by an anonymous engineer on Atari's development
staff). My PC board has "REV. B" written on it. I'm not sure what the
different rev's are, but I'll give warning to be careful about following these
explicit instructions if your board is not REV B.

A couple of side notes:

1) I'll be happy to answer any questions about the memory upgrade (another public service) as long as the volume isn't too high. I'm augenbra@udel-scrooge.arpa

2) When I followed the (wrong) instructions that I got from the bboard the machine did not boot. As a matter of fact the screen would turn on in white or blue for one second and then go blank again. I didn't even get the boot screen. I then figured out that the instructions were wrong and made the corrections that were necessary and the machine booted. The moral is that following the wrong instructions (for anyone out there who did) is not fatal to any component, and you can get things working again by correcting the mistake.

3) I only upgraded one machine, using those old instructions. The moral of this is that I've never used the document below and it could contain mistakes. I'll read it through pretty well, though.

4) I take no credit for this upgrade. I used some of the text from the original document word for word. I forget who posted the original instructions, but he deserves any credit.

cut here----------

1 MEG MEMORY UPGRADE FOR THE 520ST

WARNING: This will void your warranty, etc.
WARNING2: This upgrade is not for beginners. You really need to have the right tools and know what you are doing to get it right. Also, if you damage the machine with this upgrade it is unlikely that you will be able to find anyone who will fix it. This upgrade involves cutting three traces on the board, so you couldn't just take out the new chips and try to send the machine back to Atari. OK, enough scare.

Tools & components needed:

16 256K * 1 RAM chips, 150 ns access time type, e. g. NEC 41256C-15 (available at Fry's Electronics, Sunnyvale, CA for $2.77 ea.)

6 68 ohm 1/4 W carbon film resistors, 10% tolerance. I used 1/2W, but I was cursing the whole time. This is because 1/2 W are really too big, so use 1/4 W if you can.

A decent soldering iron. Needs to have a tip that is the same size as an IC pin or smaller. A Weller temperature controlled station would be perfect, but I got along with my Ungar Princess.

Good quality resin core solder (thin)

A few feet of thin (24 guage is good) insulated wire

A few feet of solid copper tinned bus wire. 22 AWG would be good, I used 24 AWG with no apparent problems.

Solder sucking equipment

Normal hand tools (screwdriver, pliers, etc)

A steady hand and self-confidence

Explanation of the modification:

U15 is a memory controller chip (Atari calls it an MMU even though it isn't). It goes inbetween the 68000 and DMA devices and the memory. Thus all communications to memory is done through this chip (someone correct me if I'm wrong). The chip knows about two "banks" of memory. Each bank consists of 16 chips. These chips may be 64K, 256K, or 1M DRAMs. I'm not sure if you can have different types of chips in the different banks. As shipped, a 520ST has one bank of 256K DRAM's. These chips have all of their address lines in common. The RAS line is also common to all chips. There are two separate CAS lines, one for the lower 8 chips, and one for the upper 8 chips. All of these lines come directly from U15, the memory controller chip. There are also 3 lines available from U15 that are currently not connected at all. They are the RAS line and two CAS lines for another bank of memory.

We are going to add bank 1 (the original chips are bank 0). The new chips will be "piggy-backed" onto the original chips. All of the pins from the new chips will be connected directly to the respective pin of the original chip that it is piggy backed to except for pins 4 and 15 which get wired to the U15 bank 1 RAS and CAS. Thus the new chips share address, data, power and ground with the old chips.

All RAS pins of the new chips are wired together and will be supplied with the "RAS1" signal generated on pin 18 of U15. The CAS pins of the 8 new high order byte chips are wired together and are supplied with the "CAS1H" signal from pin 22 of the memory controller, and the 8 new low order byte chips are wired together and supplied with the "CAS1L" signal from pin 21 of U15.

Reference:

The existing memory chips are numbered from U16 to U45. There are some gaps in the numbering, but they are numbered in increasing order. The high order group, from MSB to LSB consists of U45, 44, 43, 42, 38, 34, 33, 32. The low order group from MSB to LSB consists of U30, 29, 28, 25, 24, 18, 17 and 16. One of the groups is used for even memory locations and the other is used for odd memory locations; I'm not sure which is which, though.

How to go about it:

Step 0: Read these instructions through, and do not apply power to the ST if the mod is half in.

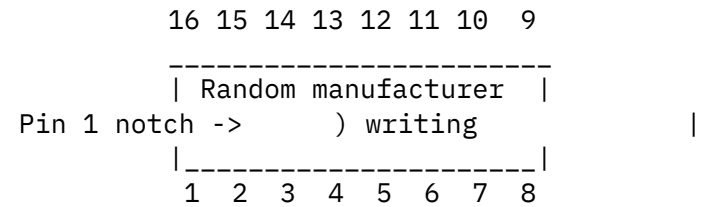
Step 1: Open up your 520ST, pull off the keyboard connector and remove the main circuit card from its top and bottom shielding. Make sure to remember which screws go where and note the keyboard connector orientation.

Step 2a: Desolder all of the capacitors next to the existing RAM chips and make sure that the holes are clear enough for the cap's to go back in easily. This step is necessary so that you have enough space to solder the new chips to the old chips.

Step 2b: Clear away any solder splatter that is sticking in nasty places on the component side of the board. This will soon be real inaccessable.

NOTE: If you damage the PC board you better fix it before going on. Things start becoming inaccessable now.

Step 3a: Take a RAM chip, and bend pins 4 and 15 (RAS and CAS) so that they are sticking up (yes a 180 degree bend). Use whatever care is necessary to keep the pins from breaking off. A rounded bend might be necessary. For those of you with poor memories (organic, not silicon), here is where pins 4 and 15 are on a 16 pin DIP. Chip is as seen from the top.



Step 3b: Place this chip on top of one of the existing RAM chips, put it on the leftmost or rightmost, whichever you prefer. Bend the other 14 pins so that it has a snug fit on the RAM chip. The bottom of the new RAM chip should be touching the top of the existing RAM chip. Now solder the 14 pins that aren't sticking up on the chip. Don't overheat, everything is static sensitive, etc.

Step 3c: Repeat 3a and 3b for the other 15 chips. No one ever said that this was going to be fun.

Step 4a: Remember those capacitors that you spent an hour taking out? You guessed it. Now you have to spend a half hour putting them back in.

Step 4b: Generally clean up the board. Look for bits of sticking solder debris.

Step 4c: Take a break, eat lunch, have a beer. You're only about half way there.

If you've done everything right so far your work should look like a combination of piggy-backed RAM chips and a bed of nails.

Step 5a: You must now take a piece of bus wire and cut it to the length of the chips. You don't need any extra length since the connection from the bus to the memory controller will be made to the middle of the bus, in a "T" fashion. Take this wire and solder it to all of the pin 4's, forming the RAS bus. Cut off any part of the IC pins that extend above the top of the wire. The wire must actually be touching the RAM chips. This is so that the wire doesnot touch the metal shielding above, i.e. so that we have maximum clearance.

Step 5b: Take another piece of bus wire and cut it to the length of the chips and wire it to all of the pin 15's. Once again make sure that it is as low as possible, actually touching the tops of the IC's. And cut off any part of the IC pin that extends above the top of the wire.

Step 5c: Cut the pin 15 bus wire in between U30 and U32, thus making the 16 chip pin 15 bus into two 8 chip buses. These are going to be the two new CAS buses.

You now have 3 buses extending above piggy-backed RAM, 2 of the buses are 8 chips long and one of the buses is 16 chips long.

Step 6: Orient the 520ST (REV B) PCB so that you are looking at the solder side (non-component side). with the row of d-rams nearest you. Find the double square pattern of pads at the 68-pin socket of the memory controller, U15 (3H-2119). The following is a guide to locating the six memory controller pins necessary to complete the wiring. It is not as convoluted as it looks. The socket is numbered CLOCKWISE when looked at from the bottom of the board (this is the mistake that I saw in another version of this document; it said counter-clockwise). The sequence starts with pin 1, the square pad (look closely) in the middle of the bottom outside row. The sequence, moving clockwise from pin 1, first on the outside square ONLY: (NOTE: the sequence ")(" means to make a 90-degree turn clockwise, e.e. around the corner)

```
1,3,5,7,9)(10,12,14,16,18,20,22,24,26)(27,29,31,33,35,
37,39,41,43)(44,46,48,50,52,54,56,58,60)(61,63,65,67
```

The sequence, moving clockwise along the inside square only, and starting with the left side of the bottom row:

```
62,64,66,68,2,4,6,8)(11,13,15,17,19,21,23,25)(28,30,32,
34,36,38,40,42)(45,47,49,51,53,55,57,59
```

Six 68 ohm resistors are used in the upgrade. 3 go to the RAS and CAS lines of the new bank, and 3 go to the RAS and CAS lines of the original bank. These series terminating resistors minimize overshoot which may damage BOTH BANKS of memory if ommitted. The upgrade will not work right if you try to get away with just the 3 for the new bank. So bite the bullet and go for all six.

Step 6a: Solder a 68 ohm resistor to pin 18 of U15, RAS1. Solder a 24 AWG stranded wire from the remaining end of the 68 ohm resistor to the pin 4 bus (RAS) of the new d-rams.

Step 6b: Solder a 68 ohm resistor to pin 22 of U15, CAS1H. Solder a 24 AWG stranded wire from the remaining end of the 68 ohm resistor to the pin 15 bus (CAS) of the new U45, 44, 43, 42, 38, 34, 33, 32.

Step 6c: Solder a 68 ohm resistor to pin 21 of U15, CAS1L. Solder a 24 AWG stranded wire from the remaining end of the 68 ohm resistor to the pin 15 bus (CAS) of the new U30, 29, 28, 25, 24, 18, 17, 16.

The other 3 resistors go in series with the RAS and CAS lines to the original chips. This means that you have to cut three traces.

Step 6d: Find the traces leading from pins 6, 7, and 8 of U15 to the RAS and CAS lines on the original chips. On my board these traces ran on the component side of the PCB from the memory controller socket downward. (For this discussion the PC board is oriented with the component side up with the memory chips towards you). My board has some of the memory controller pin numbers printed on the board, specifically the numbers 1,9,10,26,27,43,60. The traces are three traces that run together straight for about a centimeter below and to the left of the pin 9 number on my PC board. They run together for maybe 2 cm altogether, but they are straight and close for only 1 cm of that. When you think you've found the right traces scrape off the green stuff and get down to metal and check your findings with an ohmmeter. If you are not right, find the right traces. If you are right, cut all three traces. That's right, make it so that there is no connection.

Now we will reconnect the three traces, but with 68 ohm resistors instead of a 0 ohm wire.

Step 6e: Connect one side of a 68 ohm resistor to pin 7 of U15. Connect the other side to the board-through solder pad that is to the left of pins 1 and 2 of U16. You will note that this connects directly to left-most of the three traces that we cut.

Step 6f: Connect one side of a 68 ohm resistor to pin 6 of U15. Connect the other side to the board-through solder pad that connects to the middle trace that you cut.

Step 6g: Connect one side of a 68 ohm resistor to pin 8 of U15. Connect the other side to pin 4 of U16. This is the last connection.

Step 7: Sit back. Use Brain. Do you feel confident about the quality of your work? No mistakes? No resistor leads shorting PC board metal? No solder splatters that haven't been taken care of? Applying power with errors might make your ST into a decorative, non-functional piece of art. OK? Either rebuild your ST into its shielding and cabinet or, or put it onto a surface clear of wires and solder remains (the better way. No way that shorting to shielding is a problem) and connect it to the mouse, monitor, power supply and disk drive. Boot it. If it boots your probably there. Test if the new

memory works by looking at the phystop variable ($42e) with SID or BASIC. It should read $100000. Also note that memcntlr ($424) now holds 5 instead of 4, and that v_basf_ad ($44e) now holds $f80000 (screen bitmap origin). Or you could try a single drive copy and check that it gets the whole disk in one buffer instead of 2.

In case of difficulty:

If the new memory does not seem to exist, try depositting and retrieving words in locations $80000 and up (1/2 meg decimal). If bit errors occur the ST bootROM did not detect the extension (it checks all bits of 512 locations by testing a pseudo random sequence before accepting a memory bank). Check which bits are screwed up and look in the reference part of this document and try to correct the problem. Note that if you get $84 $80 $84 $80 in all memory at $a00000 and above it means that you didn't cut the traces on the board right. Check those traces with an ohmmeter across the resistor. It will read 0 ohms if the traces weren't cut right.

If the machine doesn't boot (doesn't even give the boot screen) you either made a wiring mistake or burnt something out (or I made a documentation mistake;If there are any differences between this document and the older one that you have seen besides the clockwise vs. counterclockwise thing, the older one is right, because that is what I wrote this one from). Look for wiring mistakes, have some rational human being check your work. Look for insidious bits of solder or wire debris. If you are determined that you burnt out something, try the memory controller first since it is socketed. Find some benevolent soul with an ST and try your controller in his. If that works, my guess is that you fritzed the memory, and you should either desolder it and test it in an IBM PC or something or cut it out and put in new memory and call it a $100 loss. You could cut your losses by buying a memory expansion card. I understand that they require you to cut out the existing chips. Sorry I don't have any better idea.

What do I do with it now that I have it:

There is a PD 360K ram disk program for a 1 Meg expanded ST. I haven't tried it yet (I just put the memory in 2 hours ago, and that 2 hours was used for writing this document), but that's why I want the memory.

I agree with the idea that writing to Apple to offer support for
the MacCartridge might be helpful to those developing this product, but
how can they be convinced that the $100 or whatever they might make

on each cartridge isn't just a loss of $2500 for the Mac and peripherals
that they didn't sell (and Atari did)? It would be great if Apple
gave the okay and allowed them to market their cartridge, but I don't
know if there are too many good reasons why Apple would want to do that.
David Small also said that selling the cartridge without the ROMs was
not something he would consider.

I'm trying to decide on a printer to use with my 520ST. I'm interested
in dot matrix primarily and want something that works with First Word since that's
the major piece of software I'll be using. Recommendations?
Thanks.

For those people who requested this information:

Data Pacific
P.O. Box 10805
Marina del Rey, CA 90295
tel. 213-821-2623

are the makers of the MacCartridge. Their flier says to write or call
for "a chance to win the first cartridge to be produced."

At an Atari demo session today at the West Coast Computer Faire, someone
from Atari said they wanted to start a rumor that they were developing
a cartridge for the Mac that would let it run ST software...

The story so far (especially for the line-eater)

Now that I have got an ST1040 (I bet it's the first in Switzerland!)
I have to think about software. Most of this newsgroup seems to be
people with early STs, possibly 520, possibly TOS on disk, probably
with the developer's kit (including DR C-compiler). It ain't me, babe!

So what do I want (beg, borrow or buy)? Answer: C-compiler, terminal
emulator with Kermit, RAMdisk, word-processor (with possibility of
accented characters), assembler, reference guide and general utilities.

So why am I boring you with all this? Answer: because the choice is wide,
and getting wider. Therefore, has anyone opinions on the best:-

C-compiler: DR (is it available?), Lattice C, Megamax, GST, other?
        Must produce good code (# dhrystones!) and be ergonomic.

Emulator: Want VT-100 (or 220), preferably with Kermit. Is anyone
        yet distributing Kermit, either on a disk or with utility
        software to bootstrap?

RAMdisk: Must work with TOS. Public Domain? K-RAM?

Word-processor: On my CBM64 I like PaperClip, but maybe with the 1040
        a WYSIWYG is nice? ST-writer is a pain to put in accented
        characters.

Assembler: PD or buy?

Reference Guide: How about the one published by Abacus: is it any good?

General Utilities: Keith Hall offers a fair number: any other offers.

I am willing to act as a clearing house for my area.
Thanks for any info, and happy 1040ing.

Mike Gerard

For professional use, we have developped an Atari ST Tektronix (tm) "ASTEK" emulator with the following features:

- to be used with monochrome system only,
- offers choice and settings by menus and dialog boxes,
  mapping of graphic space: 1024x780 -> 512x390,
  full emulation of 4010-4012,
  emulation of 4014 vector mode,
  interprets some sequences of 4105 format: line attributs, marker type, fill area style. Dynamic drawing is possible without refreshing the entire screen.
- enables graphical input with mouse and keyboard,
- offers choice for local character size (between the three system fonts),
- presents text in one or two-columns mode (without scrolling) in Tek mode,
  Save of graphical screen (now in Degas format) on disk file for later local enhancement and hard-copy.
- return to alphanumeric (VT52) mode with vertical scrolling at any time,
- break signal capability....

The first version of ASTEK was presented on the Atari Software Show in Paris (18 march 1986) and a copy was given to Atari Corp via Atari-France to be evaluated. Many professionals have showed interest in this product.
Therefore, we plane to distribute it with charge (ranging $100-$150) should Atari Corp. decide not to act as distributor.

I beg your pardon. I answer all my mail and do not refuse information except that which is sensitive or confidential. If I were so unconcerned about your problems why would I have posted the RAMDISK in the first place. Your request for info was either lost getting to me or I could not figure out your return address. I suspect the former.

Subject: Distribution theory

    I have had a lot of interesting
people online the Club Network lately,
many who had had a chance to chat, and
I seem to find STRANGE distribution
channels coming from Atari.

   Having talked to people from all
over the country, it does seem that
Atari is attempting to starve out

distributors by PURPOSELY delaying shipping to them. While I can empathize with Atari preferring dealers deal directly with them, Atari's "severe" (to many smaller stores) policy of a $3000 minimum order means dealers are essential to these smaller firms who want Atari's to sell. In fact, the local Atari store is selling as many ST's as it can get it's hands on. If it can get any, that is.

Also, EVERYONE but Lansing, MI seems to be able to get ROMs. Gee, I thought Lansing, being the capitol of Michigan, at least -sort of- qualified as a major population center (culture is not an issue...) and as such, might deserve SOME attention. But I guess not. And here was have one of the biggest (only?) automotive plants too (makes the Pontiac Grand AM, Olds Calais etc. body) which means a large group of at least somewhat educated buyers.

Perhaps it's because the only Atari dealers in town have to resort to - god forbid - dealers, because of the size of computer operations locally, but if this is the case, then the "policy" Atari seems (note "seems") to have formed is going to cost them a city. If Atari doesn't up the quality of service and shipping soon, especially with TOS on ROM, of which today we got our ONE AND ONLY, no exxageration, set in all the city JUST TODAY, then this city (with it's strong IBM/GM PC-compatible drive) is going all IBM PC compatible. Period.

I guess I can't disagree with Atari wanting some working capitol, but if they want the dealers out of the picture, they ought to at least chin up and say it.

I use my ST as a dialup terminal for a VAX 11/780. The VT52 emulator is
not too bad once you have the proper termcap.

I am the person who offered to copy three disks worth of ST software for
anyone wishing it. I would like to report that so far this operation is
going very smoothly. I get an average of one request a day and everyone
has cooperated nicely by sending postage, a SASE, packing material.

Therefore, the offer still stands. The following items are on the disks:

Languages: XLISP, TINY BASIC, PROLOG (built on top of XLISP) and, until
I hear an objection from Mr. Bradley, the FORTH I posted
earlier.

Accessories: Breakout, Puzzle, CLI, Clock, Fontload, 4 RAMDISKS, Snapshot,
File, memory, disk editor (plus a few others)

FONTS (for fontload.acc): about 30 fonts (inc. Greek and Hebrew)

Utilities: drive checkers, icon editor, microemacs, disk editor, crash
analyzer, fast copier, pack/unpack (for transmission of many
files (like shar but not as sophisticated)), squeeze/unsqueeze
(we all know what that is, right?), UUDECODE, CLI, working
spooler, xmodem/vt52 emulator (from CWRU and better than anything
I have seen sold in stores), utility to change volume labels on
disks (surprizingly handy once you have it) plus a few more.

C Source: all XLISP, XMODEM .c,.h

Docs: XLISP, microemacs plus some utilities (not a complete set since I do
not have a complete set.

By the way I received, copied and sent back disks to the following people
who I could not reach using CSNET: DeMillo, Skehan, Moore, Chiu, Gibson.
I hope you got your disks ok.

Notes: The FORTH only works with TOS in ROM.
The FONTS only work with TOS in RAM.
Put all fonts on a separate disk, hit font accessory - follow prompts
TOS in ROMers need only have a second boot disk with the
fontload.acc (renamed to deskn.acc where n is an integer between 1
and 6) and TOS.IMG (hope you did not throw that away).
The INTERSECT RAMDISK is hard to set up as has been pointed out.
It has two problems: you must cycle power on the 520ST module (not
too serious - the chips should be able to stand it) to reboot and
it uses 50k more space than it should. But it is very handy since
it can be resized and removed easily. If I need as much of my 1 MEG
as I can get (for C compiles) I use the 650k or the 709k ramdisks
(from the ATARI BBS). These beauties take almost no extra space
but are always in place. To set up all RAMDISKS create drive icon
D and save desktop (more details in docs).

You may send your disks, SASE, packing material to

John Franco
2535 Spicewood Lane
Bloomington, IN 47401
USA

Special requests honored as long as demand remains steady.

Note: If you are mailing from outside the United States please enclose
       $2.50 US instead of postage (Bloomington, Indiana is located in
       the middle of the USA and people here have only vaguely heard of
       places like Germany or France so you can imagine that sending your
       native currency to me, as pretty as it might be, is useless) or one
       disk (disks here in Bloomington cost between $2.00 and $2.50 in
       packages of 10 - what do they cost where you live?)

Remember: You are taking a risk - your disks might be lost or damaged in
          the mail and I cannot be responsible for that.

Also: If I get too many requests I will raise a flag on the net until
       I am caught up.

I just went through the printer selection process myself recently and ended up
with a rather expensive but really nice printer, the FUJITSU DL-2400C. It is
a 24-pin dot-matrix unit. Its letter quality mode is extremely good,
definitely good enough to send out business letters or camera-ready book
manuscripts in, in my opinion. Speed is 216 cps draft at 10 cpi and about 288
cps draft at maybe 15 cpi (a little compressed). It really flies along in
draft mode. Letter quality mode is about 96 cps, which is still far faster
than most inexpensive printers. This unit supports IBM and Epson graphics, so
should plug in and play with most mainstream software. It worked perfectly
with my Atari 800XL and Speedscript word processing software, which certainly
was not tailored to this particular printer.

It also has both parallel (Centronics) and RS-232 serial ports, selectable
from the front panel. The serial port parameters can also be selected from
the panel. A bidirectional tractor feed is included in the basic price
(better check this on all models). Automatic cut-sheet feeders are available
with 1, 2, or 3 bins. (Letterhead, memo, and second-sheet can be loaded all

at once with 3 bins.) Paper handling is superb. Dot registration on fine graphics drawings is absolutely perfect, though probably you would have to do such things in unidirectional mode to match the perfection of the demo printouts. This machine is one of the few I have seen that you can run with single sheets without unloading the tractor mechanism. Press the "unload" button and the tractor feed paper backs out of the way so you can feed single sheets. Press "load" (=form feed) and it moves back up into position with the top of form automatically aligned with the print head and ready to go. You can also form feed the paper so you can tear off what you just printed, then reverse-form-feed it so you don't have to keep wasting sheets of paper. Now that I am paying for the paper myself, this really hits home!

This printer also prints in seven colors! I will be paying around $890 for it, but was quoted a price of $782 without color. I don't know what I need color for, but I thought for ~$100 more, I decided it would be fun to have and for some home business applications, you could save that much real fast by not having to go get letterhead printed up!

Some other amazing features are: Hex Dump mode. Ever want to print out a binary file without skipping half the characters and blowing away your printer with the others. This unit will do it. How about automatic skipping of perforations? Want to set a left margin to print some text that has no indentation at the left? No sweat, a few keystrokes at the panel does it. How about automatic right justification? Proportional spacing? Download your own font? The unit has two standard ones built in which by the way take care of most of the European languages. There are also plug-in font cartridges, including I believe a RAM cartridge that you can program any way you want. Any of the fonts can be rendered in italics, bold, double width, double height and various other options by means of software linear transformations in the printer. With all this programmability, it's a good thing the self-test mode starts by printing out all the options you have selected!

In case you wondered, I am very definitely a FUJITSU DL2400 enthusiast right about now!

Other 24-pin units worthy of consideration are the Epson LQ-1000 or 1500, the NEC P5 or P6, and a Toshiba model I don't recall the number of (maybe P324?). Oh yes, there is a Star Micronics 24-pin unit also, which Analog magazine brags about with regard to the print quality of their program listings these days.

If super letter quality is not important to you, the Epson RX-85(?) would be a good choice. It is a 9-pin unit, but manages to come up with pretty darn good NLQ output. It is about as fast as the FUJITSU. A friend of mine who is very knowledgeable bought one and is very pleased with it.

For El Cheapo models, the Panasonic KX-1091 is widely regarded as a "best buy" with good NLQ output and a low price of about $230 mail order. Higher priced Panasonic models (1092, 1093) have higher speed but about the same quality. The Epson FX-85 is another fine little printer, Okidata is widely mentioned as a good choice, and oh yes, the Centronics GLP ("Great Little Printer") is an inexpensive choice that my FUJITSU salesman suggested. He seems to give good advice, so I suppose it would do well by you.

I think any of the above would serve you well if the speed/price tradeoff suited you. Personally I am "sold" on the 24-pin approach, as the output quality is a cut above "everybody's dot matrix printer" and people tend to\be startled to learn that it is a dot matrix unit. And the ability to print in color is rather dramatic! Finally, if you do a lot of printing of long drafts and your time is as limited as mine, you REALLY should get a high-speed unit that can print drafts at 200-plus cps. It's amazing how quickly you get used to this speed and how painfully slow other people's printers seem when you do!

.

I originally posted this (a month ago) to net.micro since our site wasn't getting net.micro.atari16. We have not had reliable news service up until now (and we now have atari16) so I am reposting to the right group. Sorry if you've seen it before.....

 Does anyone out there know what is required to convert the dma port on the ST to a real SASI interface. I would like to use a fast 40mb st506 drive and sasi interface I already have on my ST. Apparently the developers drive has a little board with a half dozen 7400 series ics plus one pal and this then connects between the ST and an Adaptec sasi controller. How about someone with the developers drive divulging the contents of the "little board" and which model adaptec controller is used?

Is there a schematic with the developers drive? Could someone
post it?

Although complete compatibility with the developer's drive would
obviously be nice I can live without that as I don't see writing
a custom device driver as a problem - so if anyone has ideas for
an interface circuit that wouldn't be 100% compatible that would
still be interesting.

BTW - I (and I'm sure a lot of other people) would like to know how
      people with the hard drives feel about them & their performance
      (and just what the price is).

Many thanks in advance for any help,

     john chapman

Can anybody out there (particularily Atari (neil?) if they are listening) help
with these questions:

1. Is it true the new 520STs have ntsc and rf modulator outputs?
   Will atari retrofit the original STs? or better will Atari provide

the necessary details so we can do it ourselves? There are unpopulated, but etched, areas on the pc board - is this what was supposed to go there?
Alternatively will Atari sell us the connectors for the video socket so that we can connect to other monitors (I for instance have I a monochrome system but I would like to be able to use a cheap rgb monitor or tv for playing the occasional game) or ntsc encoders.

2. Will Atari sell the connecctors for the hard disk and midi ports?
Has anyone found an alternative source for any of these connectors?
Is there a source of blank rom cartridges (everything but the proms)?

Thanks in advance for any help anyone can give.

I am posting (to net.sources) the C source to a 'make' utility.
I will mail uuencoded executables to anyone who doesn't have access
to a C compiler on the ST.

Help! The local electronics store just finished installing
the second upgrade in my ST. On boot-up, a ram-size program shows
about 901-902K available. Using MDISK, I allocate a 720K ram disk and
place the development C compiler (all 3 programs) and a source file
in the ram disk. I start compiling and when the second pass of the
compiler is to be loaded, anywhere from 2-4 bombs consistently appear.
If I reboot, and allocate a ram disk < 300 K, the source compiles without
error.
  The upgrade was installed with resisters and 150 ns. rams. It appears
that the larger ram disk forces the compiler to be loaded in the upper
512K of ram. Does the above description indicate an addressing error?
Is the MMU chip bad? I noticed that when pin 18 of the MMU chip (RAS)
is touched with an oscilloscope probe, the screen goes bananas. The
same thing happens when the RAS pins of the upgrade are touched.
I sure would appreciate any help on this one.

         thanks,

Roughly quoting from PC Products magazine regarding Infocom, Inc. and
its venture into the business community with a DB product called
"Cornerstone:"

> "...although Cornerstone was received favorably in the trade press,
> the $495 package failed to attract enough attention to survive in
> the tough and un-gamely business software market. The result:
> Infocom reduced the price of its software to $99. A few days later,
> it was announced that the firm was acquired by Activision...for
> a reported $7.5 million stock swap."

The article goes on to say that the development - and flop - of Cornerstone
drained enough of Infocom's resources that they had to let 65 employees
go, and this is part of what made it an easy target for a takeover.

This may explain why I haven't received my "New Zork Times" lately. Also, does
this mean that all future "Infocom" games are actually coming from the
"Mind of Activision"?

Depressing news always makes me thirsty...

I haven't seen any atari news since the net.micro.atari8 and
net.micro.atari16 newsgroups were created.

This is a test message.

Would someone somewhere please look into the problem.

I think I have found a slight bug in the handling of the
screen dump to printer capability. The situation is this;
I have written a program that does some extensive graphics
work on the screen in an iterative fashion. In order to

prevent the user from seeing the mechanics of the update
on the screen, I have used careful manipulation of physbase
and logbase so that the system is never displaying the
screen that is being updated. That is, I keep two copies
of the screen memory. While the update is taking place,
physbase points to the saved copy while logbase points to
the screen in which the updated data is being computed.
When the update cycle is complete, I swap the pointers, copy
the updated data to the save screen, swap the pointers back
again and begin the next update. The result is a screen
that changes instantaneously as far as the user is concerned.
All of this work 100% as expected and I get a crisp, virtually
instant change from one cycle to the next.

The problem came when I tried a screen dump to my printer. The
output contained a picture that was partially updated. I assume
that this means that TOS did the screen dump from the area whose
address was found in the logbase pointer.

I believe that the screen dump routine should be using the
physbase pointer, as all I have read implies that the screen
dump capability should give you a printout of what is visible
on the actual screen.

Have I found a bug? Is there any way to fix it?

PS The machine is a vanilla 520 ST with TOS in EPROM.

Considering how upset Apple got when GEM looked too much like the Mac,
I don't think that they are likely to want their dealers to sell the
ROMs, and I don't think that any dealer who sells ROMs will be a
dealer for long. I would expect them to start requiring dealers to
only sell complete Mac logic boards, and only when someone brings in
a complete Mac logic board, or has a very good excuse why he can't.

This of course doesn't mean that this product will never come to
market. It just means that if you want it, you should buy it as
soon as possible, and get your ROMs while you can.

I just couldn't let that one go by. "Not public domain in the United States"?
Supposed I get a public domain copy in Germany and bring it here?
Does it cease to be public domain? How can its US copyright be retained
when it is freely available to "the public"?

A question about MacCartridge:

Did I miss something? Why should *anyone* care about Apple's approval?
If the thing was made *wothout* any Apple software or hardware, what
legal claim do they have to prevent this fellow from selling them?

There's a thousand-and-one IBM PC/XT clones on the market, as well as
a hundred-and-one UNIX look-alike systems, as well as...

Apple tried to stop distribution of GEMDOS, and they lost...and they
should have, look-alikes and compatable components are *not* copyright
infrigements...at least not the last time I looked....

Subject: ST online color graphics NOW!

Well ST lovers, your number 1 BBS imperialist, in yet another attempt to bring the entire ST world under the Club Network's roof (and thus make a crowded but very aimable set of BBSes) brings you enligtening news. Not to be daunted by PC's with ANSI, we have already explored the ST's inherent VT52-extended (Our name- "ST52") escape sequences to create pleasing, pretty, and otherwise fun color graphics on the Club Network BBS's.

However, I was suprised (and disappointed) to find that a major title like ST-Talk does NOT support the ST52 with it's "VT52" mode! Therefore these colors and windows and boxes are lost - solution: heck with ST Talk, it doesn't redial anyhow, so we flipped over to the free, standard VT52 terminal program with the ST and -presto-, living color.

We are now faced with a dilema though in that, I would LOVE to be able to go into 16-color mode and have 16 colors for the graphics, but of course lo-res mode for the ST means, (god forbid) ** 40 colums! ** If we create a 16 color menu system, people calling in in medium-res will get the colors but the colors will "repeat" (only the lower 2 bits count in medium res.)

We therefore, on our PD terminal program, have considered 2 options. A.) Create an 80 column driver for the lo-res mode, which we CAN do, perhaps even reasonably, or B.) hold off, because we also had worked out a complete spec for remote GEM, so that you could (in theory) log on to a complete, windowing GEM environment. This, however, would be a complete terminal program and while we're at it if we're going to do the whole thing we might as well make it incredible.

Either of these options will, of course, mean the user will have to have "our" program in order to see graphics. However my whole idea was to create a sharp looking color graphics display using the ALREADY DEFINED ST52 codes.

Inasmuch, terminal program authors, I beg of you - PLEASE use the standard CONOUT features. At least in SOME mode! It's color graphics just a simple call away, and with the success we've had so far, I can tell you folks ST color graphics WILL be the thing of the future, or we wouldn't have jumped on it so fast. It, when well done, looks great.

If you'd like to get in on this, we'll be playing with generating color graphic "pictures" all week, and will be developing more and more ST-specific online graphics that you can access as easy as your VT52 accesory. Drop us a note online the ATARI ST/TT base and we'll include some of the early graphics in the messages so you can just read through and see what happens.

Graphics ho! Color ho!

I have used the ST as a terminal to a VAX/VMS system and a VAX/UNIX 4.2bsd system. Seems to work nice on the bsd system, but I can't find anyway to put the keypad into application mode to use with EDT on the VMS system. Also on the VMS system the built-in emulator doesn't answer dec's set term/inq command, so you must explicitly set the terminal to a vt52.

Same is true for ST-Talk, another problem(?) with ST-Talk is due to the information lines the useable screen length is only 21 lines. It does however answer the terminal inquire correctly.

There have been a couple terminal programs posted to net.sources and/or mod.sources for the ST, but I have no experience with them.

If anyone knows how to put the keypad into app. mode PLEASE tell me!

The problem is that it DOES use Apple software: the cartridge takes
the PROMs from a Mac, adds some code to reroute things for the ST
hardware, and plugs into the ST cartridge port. Since they're using
the Mac ROMs, they DO need to clear it with Sculley et al.

While I concur on the GEM issue, this is a clear case of re-use. I
hope Apple clears him, but I suspect they won't.

The ST works nicely as a terminal on a VAX, at least under unix. There is,
however, a bug in the VT52 emulator in handling cursor movement in column 80.
This makes a screen editor like vi get horribly confused when you are trying to
edit files which contain some lines of exactly 80 characters. I would expect
that the VMS screen editors would evoke the same problem.

I guess you could make up a special '520st' termcap entry, but neither the
stock vt52 or H19 entries work correctly.

There are also some adjustments in the monochrome monitor you or your friendly
local TV repairman can twiddle to adjust the size of the displayed screen.
However, they are compromise adjustments - if you expand the screen to the
full monitor size, you will start to see some pin cushion effect, see the
scan lines, and minor focus differencs from center to corner. On the other
hand, you get a more readable text display.

A simple 3-wire connection using pins 2,3, and 7 seems to work nicely, and
9600 baud is no problem...

Thank you for the improved docs. I cannot understand why more people aren't interested in upgrading 520s and saving $250-$300 over buying 1040s (you can get a color system for as low as $775). Could the reason be the reduction in number of cables?

  In part answer to my own question about the screen size on the monochrome moniter: yes atari meant for the viewing area to be smaller than the physical screen size.

  However, there is a rather straight-forward way of fixing this which is described the April '86 issue of ST Applications. If you can't get a copy and want to know how to do it, I'll email

(or post, depending on whether there are more than 3 mono systems
around) a summary. BTW, this fix voids your warrenty (so what doesn't?).

  Another question: The display on my mono moniter becomes "jittery"
after the system has been on for about 10-15 minutes. The problem
disappears after another 10-15 minutes. ("Jittery" means that the
horizontal hold appears to be off, pixels alternate between their
proper location and one location to the right or left.) Any ideas
or previous experience with this problem? Is it in the moniter or the
ST? Should I consider this grounds to try and return the ST?
(And get another, of course!)

  I saw a 1040ST this weekend. As a previous poster said, it makes
a whining noise that I would find intolerable for more than a
few minutes. Any explanations or fixes? (Me, I'll have 1Meg after
the warrenty on my 520 expires!)

I have noticed that the arrow keys don't seem to work in the VT52 Terminal Mode.
Also the function keys, as well as the cursor keys, don't seem to produce unique
or distinguishible codes. Has anyone else noticed this?

Thanks for the info,
Jack Bicer

Weren't the CD roms with the entire (Grolier?) encyclopedia supposed
to be out for the ST in the 1st quarter of 86. Is atari still planning
on selling the drives and encyclopedia disk?

Well the St has been out for some time now. Has anyone heard
of OS/9 implementations for it nearing completion? If microware
is on the net perhaps they could comment.

It would be ideal if it came on a cartridge so that you could boot
it up when you wanted it or just use the machine as is if you wanted
to run an existing ST program (I know you can do the same by booting
off floppies - I just like the idea of being able to plug in the OS
just like any other important computer accessory :-).

Here is the 1st Word printer driver for Panasonic printers.

----------cut me----------

This 1ST_WORD printer driver is compatible with the following printers : PANASONIC (1090,1080,1091,1092,1592 1093. As well as these ROLAND (1010,1011,1111). Since the light function is not available on these printers, I have substituted for proportional mode.

Here are a list of changes and additions :

LIGHT mode (F4) is now set for Proportional mode

In the special character menu on the second line there ten characters which for lack of a better term I will call LCD characters, like a calculator display's. Since only the Atari printer is capable of reproducing these I use them to enact special funtions like :

LCD (0) NOW used to turn ON ELITE pitch printing
LCD (1) NOW used to turn OFF ELITE pitch printing

LCD (2) NOW used to turn ON CONDENSED printing
LCD (3) NOW used to turn OFF CONDENSED printing

LCD (4) NOW used to turn ON ENLARGED printing
LCD (5) NOW used to turn OFF ENLARGED printing

LCD (6) NOW used to turn ON DOUBLE space printing
LCD (7) NOW used to trun OFF DOUBLE space printing

LCD (8) NOW used to turn ON 1 1/2 space printing
LCD (9) NOW used to turn OFF 1 1/2 space printing

OPERATING NOTES:

1: It is impossible to print both in ELITE mode and NLQ
   at the same time.

2: When using the double space feature place the LCD 6
   before the line where you want duoble spacing to
   begin. And place the LCD 7 where you want it to end.

For example if you want "The lazy dog" to be double spaced :

ON S C R E E N	ON P R I N T E R
Mary had a little 6	Mary had a little
The lazy dog 7	
	The lazy dog

Is there some way to convince a 1040 to read a MacIntosh disk,
and vice-versa? Nothing fancy is needed, just pulling off bytes.
My department has Macs connected to its Vaxen, and I intend to
buy a 1040. It would be nice to use a departmental Mac as a
disk drive to up/download files between my 1040 and the Vaxen.
Thanks.

I was hoping that the ST printer port was bidirectional, but I have seen
no documentation for it. The ST manual shows only one set of data pins
on the printer socket, and the developer's kit only talks about writing
to the printer, not reading from it. So:

What are the pins on the printer socket for doing input to the ST?
What does the software interface look like? Is it the obvious thing
(using one of the BIOS input routines with the the printer device)?

Activision is about to release "Music Studio" for the ST. This program lets
you create and edit sheet music using the mouse. It plays music through the
internal sound chip or through MIDI devices. It also includes a printout
feature. I personally think this is a GREAT program.

Despite Jwahar R. Bammi's rebuttal, the problem described (no printing
of statements not ending in '\n' until explicit buffer flush) is a bug.
It is possible to use fflush(stdout) to get around it, as he describes,
but that is not how most standard library printf()s require things.
Sorry, Jwahar.

I can sympathize with franco@indiana about posting binaries. Some sites are
bound to get corrupted files and then requests pour in to the sender for

a re-post. (I have to admit to being guilty of this also.)

The solution, of course, is for some site to volunteer space to keep public domain software, ala Simtel20 for CPM and IBM software, accessible by anonymous FTP.

Since the system that I'm on usually has 1Mb of free space I am sorry to say that I am in no position to volunteer so please don't flame me.

Would you all please think twice before sending messages,
especially cc's, to the entire list.

When responding to a question it is often appropriate to
respond to the sender ONLY. Adminisstrative messages should be
addressed to -REQUEST.

Thank you.

No, no. I have yet to see any printf do any automatic buffer flushing
on micros, minis, or main frames.
Jwahar was right!

The truth is, Allison-Erwin is no longer an Atari distributor. They were
in "limbo" for a short while, during which time we were evaluating the
relationship with each other. They never received 1040ST's during this
period, and will not receive any. The dealer in question should either
contact the local rep or a different distributor.

The ROMs are currently out of stock, with a shipment on the way right now
from Taiwan. We should be able to fulfill dealer orders shortly. End-users
have been able to order direct when they were in stock, but not recently.

In reply to WINDGARDs plea for information on 1040s (no I am not an Atari rep):

   You dealer is unhappy about a $3000 minimum order for direct orders from Atari? This seems a bit strange if he is actually having all of the holdouts you mentioned. $3000 is approx 3 (three) 1040STs. This doesn't seem to be an overly large minimum order.

   About Ataris (alleged) program of starving distributers to get directo orders, if true it is not nice. But does your local shop owner really know how hard the distributer is working to get them?

A message recently contained a question about scrolling windows; a reply concerning how to do so in an active window (hence on top); and a final plea asking "But what if the window *isn't* on top?".

As far as I know, if the window is not on top, it is not active, thus you need not be concerned with scrolling it.

What sort of situation do you have where you require scrolling for an inactive window?

I received a letter from GST with information on bugs in 1st-Word. Letter was dated 28 Jan. 1986. Here is a summary:

Initial form feed: No, it cannot be suppressed. Fixed in Ver. 1.04.

Cannot pause between pages: Fixed in 1.04.

Pitch changes: Not supported.

Printer control codes: Cannot be imbedded in text. Must be built into the printer driver.

Filename appears at top of page: To suppress, click on "layout" from FILE menu, then click OK. Fixed in 1.04.

Double line spacing: Not supported in Ver. 1.01. Fixed in 1.04.

Multiple copies: Not supported. New product called 1st Word Plus will
have it, along with mail merge.

Text style lost in block operations: Not yet fixed.

Incompatibility with ST Writer: Yes, they are incompatible.

Lines: 16

The vt52 emulation mode of the 520ST leaves a bit to be desired, and I
have been able to improve things by using a different termcap file.
The following file sets my TERMCAP variable with the command

```
     source st.tc
```

under csh, or you can pull out the termcap entry and get it installed in
/etc/termcap:

```
setenv TERMCAP "st|
520ST:al=\EL:am:bl=^G:bs:cd=\EJ:ce=\EK:ce=\EK:cl=\EE:cl=\EH\EJ:cm=\EY%+ %
+ :co#80:cr=^M:dl=\EM:do=^J:ho=\EH:is=\Ee\Ev:kb=^H:kd=\EB:kl=\ED:kr=\EC:ku=\EA:le=
^H:li#24:md=\EbB:me=\Eq\EbC:mr=\Ep:nd=\EC:nl=^J:pt:rc=\Ek:sc=\Ej:se=\EbC:so=\EbA:s
r=\EI:ta=^I:ue=\EbC:up=\EA:us=\EbB:ve=\Ee:vi=\Ef:vs=\Ee:"
```

There are a couple of gimmicks, such as using colour for standout mode.

This is not perfect, and I have trouble with the last line on the screen
-- if anybody has improvements, plese post them.

I also have a corresponding terminfo file -- I don't use it on this
machine, but if anyone wants it I can mail or post it.

How about a windowing terminal emulator? You would have several windows
on the ST, and a protocol for multiplexing several logical connections
over one serial line. On the host, you have a driver for multiplexing
the output of several processes onto one line.

In this situation, it would be easy to want to have output in several
windows at once.

Or how about a terminal emulator with a built in editor? It would be nice
if I could edit some text in one window, and then tell the terminal
emulator to send it. While I am doing this, I would still want to see
any stuff that comes in from the host, even though that window would
not be on top.

I have posted the source to a simple graphing program (makes
line and point plots with labelled axes, plus a little more)
to net.sources. It was written specifically for the AT&T 7300,
and has a number of 7300-specific calls. However, these are
only to set up a couple of windows on the screen - the rest of the
pgogram, including all the actual graphics, uses GKS function
calls. Therefore, it ought to be able to be ported to any
machine with GKS without too much hassle (of course, the
7300 stuff will have to be replaced by YOUR machine's versions,
but there isn't that much).

The posted source is in a shar-format file together with Makefile
and a manual page that can be formatted with the -man macros.
It's pretty readable in un-nroff'ed form, anyway.

If anyone has questions, please let me know - I may be able to help.

     The question I originally had was for desk accessories such

as the Apple Macintosh's clock accessory. This happily can sit on top of your window, and screw up your raster map. I guess GEM just said "no way" to this type of background accessory, so we don't have to worry.

     As far as scrolling inactive windows, the overlapping windows will screw up your scroll. Why not make the window active, scroll it, and then make the original active? Also, if nothing overlaps it, you might be able to scroll it anyway (I forgot how copy raster was called, so I can't guarantee it)

I have only seen this behavior on one out of about 5 machines I have worked on. Since, I believe, this is not documented in K&R (and in most Unix manuals) the nomer of "bug" does seem correct. It is just a widespread and familiar one...

The price is only true for the 256K Amiga with built-in drive and color
monitor. It seems like they have a warehouse full of color monitors and
are looking to get rid of them, since most Amigoids have been acquiring
Sony or other better-quality monitors. According to Commodore, this offer
expires at the end of May, about when the overabundance should run out.

If you want to be sure to get the FONTLOADER and FONTS intact send a
disk to me with your request (for fonts) and I will copy everything
onto the disk and send it back. Please include the packing material
you wish me to use and make sure proper postage has been affixed to it.
Also, you might want to write your name and address on the package to
save me the trouble of doing it.

Just because MOST standard library printf's do not buffer output to the
terminal does not mean that that is the only correct way. This is
implementation-dependent, and anyone who wants to write portatble code
should use fflush, even if it is not required by the library they are
using.

Summary: Horrible Aztec C BUG!!!

Just discovered a pretty gross bug in the Aztec C for the Macintosh.
If anyone uses the realloc function, expect random, devestating bugs.

The realloc function is supposed to change the amount of memory gotten from
a previous malloc. However, Aztec C (I looked at the sources, which are
included) implements this by first freeing the old block of memory, then
mallocing the new memory, and finally moving the old data to the new memory.
OF COURSE, ONCE A BLOCK IS FREED, ITS DATA CAN BECOME GARBAGE. In fact
on the Macintosh a subsequent malloc call after a free often causes the heap
to be compacted, expanded, etc.. each of which can trash the data.

The reason this code is written this way is a holdover from Unix, which
promises not to compact under certain circumstances.

The workaround for this is to call malloc yourself, then move the data, and
finally free the old block. The problem with this is that it requires twice
the memory of a realloc, because we have to have the old and new blocks of
memory at the same time. But at least it doesn't crash.

Their realloc routine may work as advertised on some systems; it depends on the internals of the Macintosh. I found the problem when my Mac program produced garbage at random intervals. Implementing my workaround fixed the problem.

Note that Aztec C is an otherwise great package. However, I bought the professional version for $500 and they didn't even include a lint. What a ripoff.

I'm looking for some hints on the Mindshadow adventure on the Atari 520ST. I have gotten as far as taking many airplane rides between Luxembourg and London, found many documents and have reached a point where I have no idea what I should be doing next. Any hints would be greatly appreciated.

New Terminal emulator: WTERM

(don't ask where the name comes from -- long story)

This terminal emulator has the following features:

     VT52 support (ie. almost upwards compatible with standard Atari)
     insert and delete character capability (nice in VI and such)
     sysline mode line
     Tektronix 4010 (tm) support

and miscellaneous other things. Written using VDI calls.

The source has been posted to net.sources.

Enjoy.

Really? Most of the printf()s I have experienced have had this "feature".

The "bug" is not in printf(). The bug is in the OS where you cannot set a NOT
BUFFERED flag.

The printer port is a bidirectional parallel port. That means the same pins
used for output are used for input. The software interface is the BIOS
input routines with device parameters as you suspected.

Does anyone know any more about the company which has developed a
cartridge that plugs into the ST, allowing it to run Macintosh software?
There was a small item on this in the March 30th San Jose Mercury computer
section and someone told me that the product works successfully with

MacWrite and MacPaint. However the obstacle facing mass production is
the approval of Apple, which seems to be necessary in order for this
company to distribute their product with the Macintosh ROMs. Wouldn't
it be possible for them to sell the cartridge without the ROMs and let
the buyer purchase and install them? I have also heard that there
will be a demo of this cartridge (MacCartridge?) at the West Coast
Computer Faire. Anyone know about that?

The function getchar() is designed to return characters from line-
edited input from the keyboard, in keeping with the implementation
of standard I/O everywhere else in the world. If you want characters
as they are typed, use the low level BIOS routines.

Summary:

I had built a detached keyboard for the ST! It uses the original ST keyboard, original keyboard top cover (bearing the Atari 520ST logo), and a few (new, but surplus) parts (see below). Hardly any electronics experience needed for this project. Most of it depends on how well you can construct an enclosure for the keyboard.

To me, the whole thing looks much classier: the plexiglass I bought was dark satin brown, and it contrasts perfectly with the STs native color.

So far, it has been in daily use for about 5 weeks without any problems. The coiled chord from the keyboard plugs into the "main" box, the mouse (and the joystick, when we have some need for it) plug(s) into the keyboard housing. If need be, it can be reassembled into the way it originally was, except for the saw cut made along the deep groove you find running along the entire width above the function keys and the 520ST logo.

Connections

  The keyboard plugs into the main board using an 18-pin connector (J12). These pins are numbered 1 through 18, one starting at the bottom (closest to the keyboard). Only five of these need go to the board; of the remaining 13 pins, one is a keyway ("pin" 2 which is absent), pin 18 is unconnected, and eleven send/receive signals from the mouse/joy0 and joystick1 ports:

Mouse	J12		Joystick1	J12	
Up/XB	1	12	up	1	7
dn/XA	2	10	dn	2	5
lt/YA	3	9	left	3	4
rt/YB	4	8	right	4	3
---	5	unconnected	reservd	5	17
fire/lt	6	11	fire	6	6
+5V	7	13	+5V	7	13
ground	8	1	ground	8	1
fire/rt	9	6	--	9	unconnected

The main reasons I moved the DB-9s to the keyboard were:
(i) I could not find a coiled chord with 16 conductors (I cannot stand external ribbon cables).
(ii) I felt the mouse and keyboard should be close.
Alas, a typical phone extension chord has only 4 conductors, and we need five:

J12
---
16   ~reset   (generated on the main board)
15   Tx Data (of U21 6850 ACIA)
14   Rx Data (of U21 6850 ACIA)
13   +5V
1   ground

Parts Needed
----
     coiled chord of sufficient length, min 5 conductors
     5-, or 6-pin DIN socket and plug
     2 DB-9s
     1 18-pin plug 0.1in pin separation (can use > 18-pin plug too)
     1 18-pin socket (can use upto 20-pin socket)
and some scrap plexiglass sheets.

Construction

Most of it is this "box" making with a few solder connections as indicated
above. To instruct how to do the construction is so tedious that I am
going to suggest the very obvious: Open up your ST, and carefully examine it
until you discover your own way of doing it. Two cautionary remarks, however:

o The plexiglass enclosure should be constructed with precision. My wood-
  working imprecision made me ruin a couple of panels before I got everything
  accurate to within a millimeter! And the edges should be real straight.

o Underneath the keyboard are a few chips; make sure you allow for them and do
  not make the keyboard rest physically on these.

Have fun!

Summary:

In article <1988@brl-smoke.ARPA> Geoffrey Sauerborn writes:
>   I have followed the instuctions to the letter. There is no such
>thing as "ST FONT LOADER" under the desk menu after rebooting.
>I still do not get "ST FONT LOADER" under the desk menu
>after rebooting. Has anyone got it to work?

<>

It worked fine for me. But my TOS.IMG will not read desk accessories unless they are named 'DESKn.ACC', so I had to rename them. With TOS in ROM, this renaming is not necessary, and more descriptive names can be used.

BTW, the font loader seems to eat a large amount of memory for some reason when it is installed upon boot-up, and can only be used a finite number of times before some limited resource is used up. Anybody else noticed this? Could this program be smarter in its use of resources? And has anybody got a desk accessory which checks the memory usage? My check so far has been the size of chunk read during a diskcopy. The Intersect ramdisk tells you, but it cannot allocate a ramdisk with TOS in ROM, so it is a little big just to spy on the size. Maybe the Intersect ramdisk could be smarter, too.

I have four Rev.2 Atari 520ST systems (*very* early revisions) and I want
to upgrade them with the TOS ROM set.
The instructions for upgrading don't seem to work on the boards I've got -
they talk about links on the ROM sockets, and I don't have any, nor do
I have the MaskROM pads beside the ROMs.
I tried upgrading one board (using Atari's instructions) and got a dead 520ST;
taking the mods out again left me with a still-dead 520ST. Sigh.
Also - I'm running one machine with two SSDD 3.5" drives. When I
replace the second drive with a DSDD drive, the machine can't see it.
The DSDD drive by itself works OK.

Anybody upgraded Rev.2 boards *without* the ROM socket pin 27/28 links?
Or daisy chained disks?
Help??

Yes, they could sell the cartridge without the ROMs, but where is
the purchaser going to buy them?

The unsqueezer binary as received at this site was definitely not a TOS
binary file. It was a section out of the middle of the "PD" Forth
system, and has nothing at all to do with unsqueezing. Perhaps the
wrong thing was posted by accident.

A TOS executable file may be recognized by the magic number 0x601a
in the first word of the file.

By the way, the "PDFORTH" system is not exactly public domain. The version
that was posted is an *very preliminary* version of a "Shareware"
Forth system that I wrote. The shareware version will be out in the
next couple of weeks. The San Leandro Computer Club will have the
new version in their disk library. The posted PDFORTH version is
ancient; it accidentally leaked out about a week after I first had it
sort of working.   The new version is much much better; it has been
been beat on, debugged, and enhanced for 4 months instead of 1 week.

The real name of the Forth system is Forthmacs, which is somewhat
related to the fact that the new version includes MicroEmacs integrated
into Forth. I'm not going to say any more because I don't want to get
flamed for advertising on the net.

Cheers,
Mitch Bradley

It took me a while to figure out the intersect ramdisk. The problem
is pretty simple.

I am one of the few (I think) that has a monochrome monitor. I
couldn't figure out how to size the ramdisk, so the silly thing would
keep crashing. I was just fooling around, and I noticed that you
change the size by pushing on little colored rectangles above and
below the numbers. On the monochrome monitor, the colored squares are
BLACK, like the background! I'm sure you color monitor guys are
having a little laugh right now.

So, I beseech (implore?) you: please be careful when you are putting
colors on top of each other, and think about us monochrome guys (both
of us). I haven't seen anyone mention this before.

By the way, Mr. Franco wouldn't tell me any more about the ramdisk
when I asked. It gets tough to answer piles of mail, its hard to find
out little quirks of programs without asking SOMEONE.

Todd Fujinaka (and I thought the monochrome system was for the
"serious" programmers......)

Apple dealers sell them. Maybe some of these "512K upgrade" companies
could take some of the business too.

Two rumors have surfaced on the info-68k list that Atari users may be able
to answer:

1. The Atari ST is running a version of CP/M-68K with GEM
   built in. (Could this be true?)

2. There exists a generic Z80 emulator (not 8080) in the
   public domain that allows 68000 machines to run CP/M-80
   programs and that this program is available for Ataris
   but is *so* generic that any 68000 based micro could
   run it. This is not to be confused with the 8080
   emulator from recent Dr. Dobb's issues.

Can anyone verify or refute these rumors?

To: info-atari16@score.stanford.edu
X-Original-To: info-atari16@score.stanford.edu

Two rumors have surfaced on the info-68k list that Atari users may be able to answer:

1. The Atari ST is running a version of CP/M-68K with GEM built in. (Could this be true?)

2. There exists a generic Z80 emulator (not 8080) in the public domain that allows 68000 machines to run CP/M-80 programs and that this program is available for Ataris but is *so* generic that any 68000 based micro could run it. This is not to be confused with the 8080 emulator from recent Dr. Dobb's issues.

Can anyone verify or refute these rumors?

  Another repeat:

  Would someone please email me instructions for a 1 Meg upgrade
for the 520ST? I would greatly appreciate any advice on how to
avoid using the 68 ohm resisters too.

  Is there a user's group doing upgrades near Princeton, NJ??

  Thanks.

Could the person who originally posted this notice please re-cite his source (includeing page number)? I checked the Merc for Sunday the 30th (which is where I thought he said the article appeared) and found nothing of this sort. I still have the Sunday Mercury News, and other issues could be found at a local library if needed. I would like to read the original article.

An Input/OUTPUT Port for the Cartridge Slot of the 520ST

By Douglas P. B. Renaux - Feb 27, 1986.

This document describes the hardware and software of a 8 lines input/16 lines output port. The circuitry is connected to the Cartridge Slot of the ATARI 520 ST.

IMPORTANT!!! - INFORMATION IN THIS DOCUMENT CAN BE FREELY USED AND COPIED. HOWEVER, NO CHANGES CAN BE MADE TO IT WITHOUT CONSULTING THE AUTHOR FIRST, NOR THE AUTHOR'S NAME CAN BE OMISSED IN THE COPIES.

Foreword

Although the Cartridge Slot is intended for data input, specifically from a ROM, it can be used as an output port. To substitute the READ/WRITE line, that is not available on the slot, I used a WRITE ENABLE LATCH. This latch is set by READING a memory location. The consequence of seting this latch is that the output latches will read the data bus during the next instruction, which will be a memory WRITE that outputs the desired data.

1 - The signals available on the Cartridge Slot

```
     D0..D15 - DATA BUS
     A1..A15 - The 15 least significant addresses from the ADDRESS BUS
ROM 3 SELECT - Active when a READ instruction accesses $FB0000 to
               $FBFFFF
   UDS',LDS' - Upper and Lower Data Strobe
```

2 - The I/O PORT

The block diagram of the I/O PORT is in the file BLOCKDIA.PI3. Circuit diagrams are in ADDRESS.PI3 and IN'OUT.PI3. If you don't have these drawings then in appendix A you can read a description of the circuit.

The circuit of the I/O PORT is standart. A address decoder enables the output latches or the input buffers when the correct address is accessed. However, the output latches are only enabled if previously the WRITE ENABLE LATCH was set.

Address Decoder:
The lines A3..A15 are connected to NAND gates that detect when all these lines are at high level. The lines A2 and A1, select one of the four outputs of a decoder.

The output of the NOR gate "a" is active when we read from $FBFFFE. To decode a read to this address we use the outputs of the two NAND gates, the output three of the decoder (active when A1 and A2 are high) and the line ROM 3 SELECT.
The output of NOR gate "a" sets the WRITE ENABLE LATCH.

The output of NOR gate "b" decodes the address $XXFFFC. To decode an access to these addresses (read or write), we use the outputs of the NAND gates, output two of the decoder and the line LDS'.
ROM 3 SELECT cannot be used here because it is only active on read.
When a write instruction accesses the address $10FFFC (non-existent in 1MByte ST's) then the output of NOR gate "b" becomes active.

An AND gate enables the output latches to read the data bus if the WRITE ENABLE LATCH is set AND the output of NOR gate "b" is active.

The output of NOR gate "b" is delayed (by four inverters) and then

resets the WRITE ENABLE LATCH, just after the latches have read the data bus.

NOR gate "c" decodes a read to address $FBFFFA, as gate "a" does, but using output one of the decoder. The output of gate "c" enables the buffers to copy their inputs to the data bus.

3 - Components

2- 4068	NAND	gates for address decoding
2- 4002	NOR	gates for address decoding
1- 4556	1 OF 4 DECODER	for address decoding
1- 4043	SR FLIP-FLOP	write enable latch
1- 4049	INVERTER	
1- 4081	AND	
2- 40373	LATCHES	output latches
1- 74LS244	BUFFERS	input buffers

4 - Expansion

This I/O PORT is easily expandable to as many I/O lines you want. Only one WRITE ENABLE LATCH is necessary if the expansion is made in a way that any write to port instruction resets the latch. Another solution is to have a reset latch address (as we have a set latch address). In this case the write to port instructions don't need to reset the latch, and you can output a block of data to several addresses without needing to set the latch in between. Only at the end of the block transfer this would be necessary.

You can have another 8 inputs by just connecting another 74LS244 to D8..D15 of the data bus.

5 - Software

To write to the output lines the contents of D0:

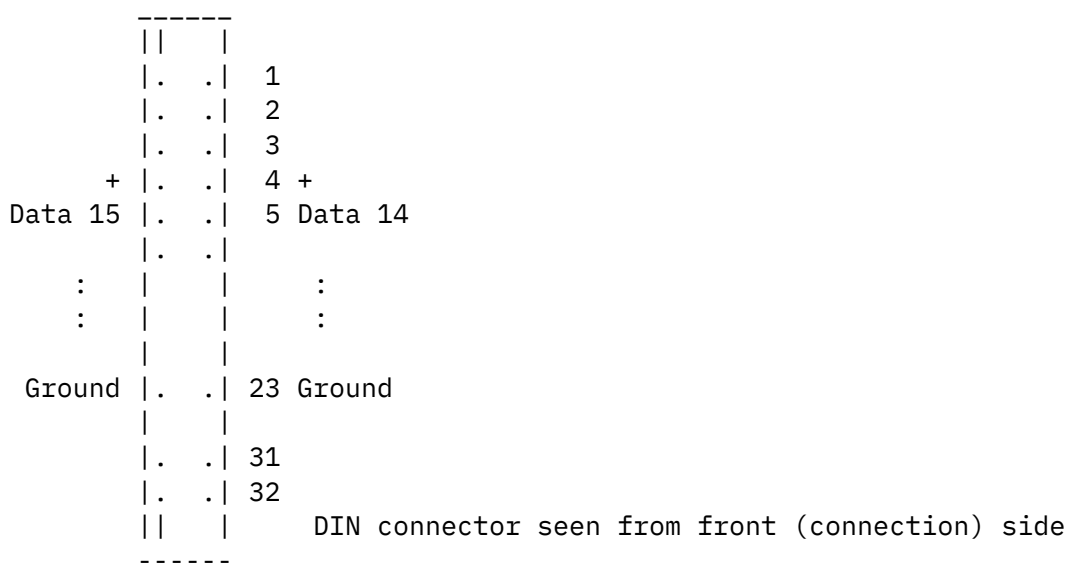
```
MOVE.W    $FBFFFE,D1     ;D1 is destroyed, latch is set
MOVE.W    D0,$10FFFC     ;D0 is latched
```

To read the input lines to D0:

```
MOVE.W    $FBFFFA,D0
```

6 - Connection to the ST

I could not find a experimentor PC Board with an edge connector that fits to the ST. So I made a convertor from the 40 pin edge connector (with spacing of 2mm) to a 64 pins euroconnector (DIN 41612). This convertor is simply a double sided PCB with 20 lines (on each side) of 1mm spaced by 2mm (center of one line to center of next line). These lines widen to 2.54 mm to fit the DIN connector. Line one of the ST goes to line 4 of the DIN connector. The tabs of the DIN connector are on the lower side.



I intend to connect some of the free lines of this connector to internal signals of the ST. Would be nice to have a standart connector between ST users. Whoever has ideas about which signals to connect and to which pin should let the others know about it.

7 - Conclusion

It is possible to open the ST !!

And this opens a lot of possibilities in hardware design. The 68000's power can be used outside the ST's box.

But a complex machine like the ST cannot be easily expanded without having information about it. The information that ATARI delivers only to software houses. Please ATARI, let everybody know about the ST. Let the POWER be available to all users.

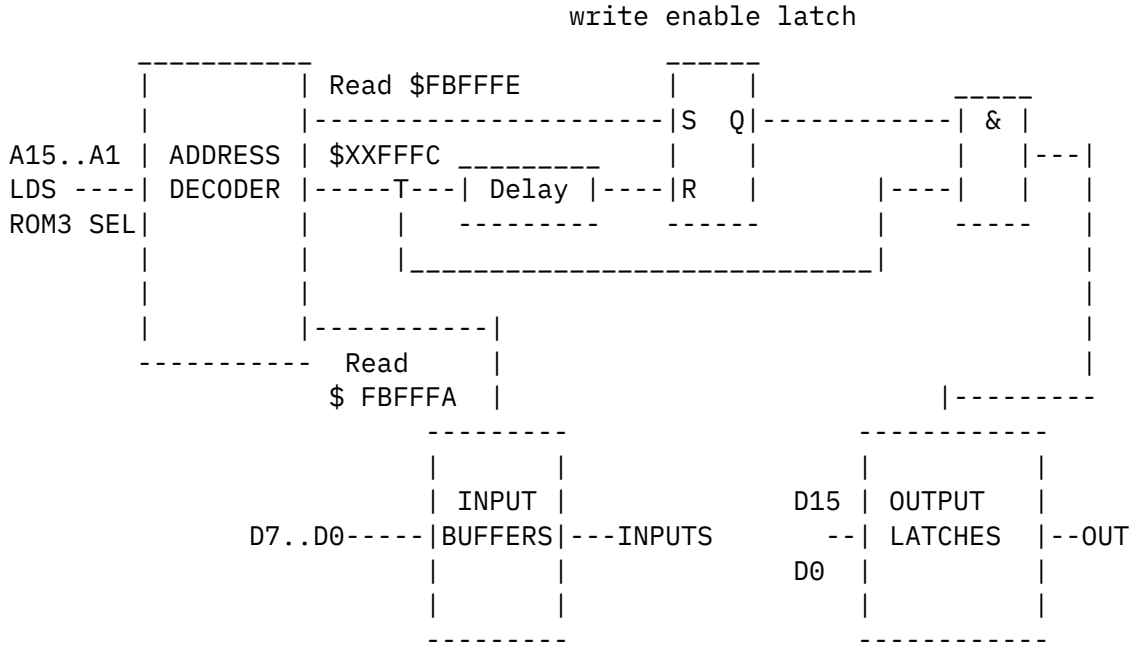
APPENDIX A

Circuit Description.

Block Diagram:



Address Decoder Description:

Address lines A15 to A3 are connected to the inputs of two 4068 (8-input NAND). Inputs are pins 2,3,4,5,9,10,11,12. One of these NAND gates has three inputs tied high. Power supply is connected to pin 14 (+) and pin 7 (ground).

The address lines A2 and A1 are connected to the select lines of the 4556 (1 of 4 decoder), pins 3 (A2) and 2 (A1). The enable line (pin 1) is tied low. Pins 16(+) and 8 (ground). The outputs of the decoder are: output 0 at pin 4, output 1 (pin 5), output 2 (pin 6), output 3 (pin 7).

The second level of the address decoding is done by three NOR gates of four inputs (4002). Two chips are necessary. These gates are labelled "a", "b" and "c".

Pinning of the 4002: inputs 2,3,4,5; output pin 1
inputs 9,10,11,12; output pin 13
power: pin 14 (+); pin 7 (ground).

Two inputs of gate "a" are connected to the outputs of the 4068 (pin 13). The third input is connected to ROM3 SELECT and the fourth input goes to output 3 of the decoder. The output of gate "a" is connected to the SET input of the WRITE ENABLE LATCH.

Gate "b". Inputs: the two outputs of the 4068s, output 2 of the decoder and LDS. The output of this gate is the line $XXFFFC of the block diagram, it goes to a chain of four inverters (4049) to produce a delay, and it goes to an AND gate.

Gate "c". Inputs: the two outputs of the 4068s, output 1 of the decoder and ROM3 SELECT. The output of gate "c" is inverted by a 4049 and then connected to the enable line of the input buffers (74LS244).

Delay chain: The hex inverter 4049 (inputs pins 3,5,7,9,11,14; outputs pins 2,4,6,10,12,15 respectively) is used. Four inverters are chained to give the desired delay and one inverter is used for the enable of the input buffer. Power is on pin 1 (+) and pin 8 (ground). Note that + is NOT on pin 16!

Write enable latch: A 4043 (SR-latch) is used. SET is on pin 4, RESET on 3 and Q on 2. Pin 5 (output enable) is tied low. Power is on pins 16 (+) and 8 (ground). SET is connected to the output of gate "a". RESET goes to the output of the delay chain.

AND gate (4081). Inputs: Q from the latch (connected to pin 1) and the output of gate "b" (connected to pin 2). The output of this gate (pin 3) enables the output latches. Power is on pins 14 (+) and 7 (ground).

Output latches. Two 40373 (octal latches) are used. Inputs (pins 3,4, 7,8,13,14,17,18) are connected to the DATA BUS. Outputs (pins 2,5,6,9,12, 15,16,19 respectively) are the outputs of the circuit. Pin 1 (output enable) is tied low. Pin 11 (enable latches) goes to the output of the AND gate. Power to pins 20 (+) and 10 (ground).

Input buffers. The 74LS244 (inputs 2,4,6,8,11,13,15,17 outputs 18,16, 14,12,9,7,5,3 respectively). The inputs of these buffers are the inputs of the circuit. The outputs are connected to the DATA BUS (D0..D7). Pins 1 and 19 (output enable) are connected to the inverted output of gate "c". Power to pins 20 (+) and 10 (ground).

I used the +5V from the cartridge slot to drive the circuit and 16 leds that monitor the outputs. (The leds are not connected directly to the 40373, but via buffers 4049).

Alot of people have received those files and alot have not. Apparently this is what happened: the files left IUBUGS (my machine) ok and were traveling merrily along from node to node until some node garbled it. Then all other nodes "downwind" of that node picked up the garbled message and transmitted it perfectly to many other sites. So alot of people have garbled files that look alike. I will not send any binaries for awhile due to a number of complaints that I have received. If you want the files I sent I suggest that you take a gamble and send one to three disks to the address below. I will copy a number of files onto those disks. (about 20 accessories such as RAMDISKS, command line interface, clocks etc., about 20 utilities such as a disk editor/file recovery program, microemacs, xmodem, (un)squeezer etc., about 20 fonts and fontloader/fonteditor, a disassembler, XLISP, the FORTH I posted, PROLOG, Tiny Basic, PD Assembler, Sources for XLISP, xmodem and a few other things, some documentation etc.) (that was about three disks worth).

My address:
John Franco
2535 Spicewood Lane

Sorry if this has already been discussed, but does anyone have experience using the ST as a terminal to a VAX? I am thinking about getting a 520ST to plug into a 9600 baud line to a VAX 750. Is the VT52 emulator included with the ST useful for this application? Are there

VT100 emulators available for the ST? Is there anything to watch out
for when wiring the RS232 port? Any help greatly appreciated.

[_does_ the line-eater really exist ?]

A few months ago I seem to recall two or three articles from people who
said that they were porting OS9/68000 to the Atari ST. A typical
message would imply that they were nearly there, and to stand by for
more details.   Without exception they seem to have dried up. I keep
looking at software lists, and watching the net, but there is no OS9 to
be seen.

Is there some reason why a port _can't_ be done?   Do the Microware
hit-men come and shoot your kneecaps ? Or, (as is probably more likely,)
have I just missed an anouncement or two.   Could someone please
enlighten me.

Cheers,
Frank.

Interesting....

    A year ago the "newsgroup/list devoted to the hardware"
    net.micro.mac threw out mac sources and binaries and CREATED
    net sources.mac.

    Now, along people come..... It's an old story.

Anybody in net-land who can help me?

I'm searching the screen memory of the ST or a pointer to it when the
ST is in command mode (COMMAND.TOS) or it is in a TOS application.
I want to do direct character
screen I/O like you can do on the IBM-PC, that means
I want to write directly into the character screen memory. I know that you
can do this in the pixel memory, as there are several hints mentioned in
the developers kit documentation, but there is no word about a
character buffer. Any hints are welcome. Please send e-mail to

Hi. I have problems...
I have followed the instuctions to the letter. There is no such thing as "ST FONT LOADER" under the desk menu after rebooting. (Only the usual things). I even tried coping the ORIGINAL TOS disk on a new disk, removing DESK1.ACC & DESK2.ACC, and rebooting with FONTS.ACC as the only accessory.

I down loaded FONTS.ACC in the UUCODED form and decoded it from my ST and I also uudecoded it on the host computer first and then down loaded (of course this time I used the "image" option for kermit). all to no avail. I still do not get "ST FONT LOADER" under the desk menu after rebooting. Has anyone got it to work?

Re: More Pascal Documentation

We have started putting up additional
documentation for Personal Pascal.
Please bear with us a we hurry to put
more documentation up, but it does
take some time since we have to send
it from the ST to our 8-bit machine,
which is running the BBS!

#24 - 437 chars 02/23/86 17:23:49
Re: Personal Pascal Bugs

Several bugs have been reported in the Personal Pascal
system, most of which can be easily fixed. A patch
program will be available soon on this system which fixes
the following problems:
  - the routine "Bring_To_Front" not found
  - mysterious numbers in the ITEM SELECTOR dialog
  - "Delete_Dialog" sometimes crashing
  - a few more fairly obscure bugs
In addition, read the following few messages for a few
fixes you can apply now.

#25 - 357 chars 02/23/86 17:29:42
Re: Rect_Intersect in GEMSUBS

The definition of the Rect_Intersect
procedure was left out
of the early versions of the GEMSUBS.PAS
file. If you file
is missing this declaration, please insert the following:

```
  PROCEDURE Rect_Intersect( x, y, w, h : integer ;
              VAR newX, newY, newW, newH : integer )
                : boolean ;
    EXTERNAL ;
```

into your GEMSUBS.PAS file.

#26 - 386 chars 02/23/86 17:31:12
Re: Bring_To_Front routine

The Bring_To_Front routine in the PASGEM library also has a problem in early releases. Due to a typographical error, the name actually used in the PASGEM file is "Brint_To_Front". As mentioned in a previous message, a patch program will soon appear to fix this problem, but in the meantime, you will have to use this incorrect spelling, if you want to use the Bring_To_Front routine.

#27 - 558 chars 02/23/86 17:35:03
Re: Cmd_Args and Filename

One more problem exists in the Pascal libraries, this time in the PASLIB file. One of the modules in that file is in the wrong position, causing undefined symbols if you try to use the Cmd_Args or Filename functions. The actual symbol marked undefined is something like "strukteq". If you want to use either of these routines, you need to tell Personal Pascal to make two passes through the PASLIB file by putting the name PASLIB in the "Additional Link Files" box in the "Linker Options" dialog. Once you do this, both routines will be linked correctly.

#28 - 168 chars 02/24/86 10:19:06
Re: Pascal FOR loop variable

To- David Duberman
  Yes, we do intend to allow Long_Integer FOR loop counters. We also intend to allow variables to occupy more than 32K of space in a future release.

#30 - 398 chars 02/24/86 10:27:44
Re: Pascal output to printer

If you want to open a file to the printer using Personal Pascal, the following procedure call should work:

```
  rewrite( f, 'prn:' ) ;
```

if f is of type "text". ('lst:' works too, as do the upper-case versions) You can also make the standard output go to the printer with:

```
  rewrite( output, 'prn:' ) ;
```

DON'T use the "reset" call with the printer, since that call opens a file for INPUT, not OUTPUT.

#31 - 414 chars 02/24/86 10:33:53
Re: Use of Get_DEdit

Some people have expressed confusion about how to use the Get_DEdit call. In order to retrieve the final value of an edited string from a dialog, you should declare a variable to hold the result:

```
  VAR
    new_value : Str255 ;
```

Then use Get_DEdit AFTER calling Do_Dialog:

```
  Get_DEdit( the_dialog, the_field, new_value ) ;
```

The string "new_value" will then contain the final value of the editable field "the_field".

#32 - 391 chars 02/24/86 10:37:12
Re: IO_Check and IO_Result

We blew it! If you want to use the IO_Check and IO_Result routines from within a Pascal program, you must declare the routines to be EXTERNAL, in order to let the compiler know about them. This gem of knowledge was inadvertantly left out of the manual. Declare the routines like this:

```
  PROCEDURE IO_Check( on : Boolean ) ;
    EXTERNAL ;
  FUNCTION IO_Result : Integer ;
    EXTERNAL ;
```

#33 - 617 chars 02/24/86 10:40:31
Re: Pascal with two drives

Some people have had difficulty telling Pascal to put their source and object on drive B:, if they have a two-driver system. In order to edit, compiler, or link a file on drive B:, select the option so you get the ITEM SELECTOR dialog, then do the following:

1. Click the mouse on the upper text field (where the directory is shown)
2. Use the keyboard to change the leading "A:" to "B:"
3. Move the mouse down into the area where the file names are shown, and click the mouse once (this tells

GEM that you have changed the directory).
You should now see the list of files on the B drive.

#35 - 795 chars 02/24/86 11:30:12
Re: STRING type w/ Pascal

There are a couple of things to keep in mind when using the STRING type in Personal Pascal. Whenever you use the STRING type, with or without a length specified, you are declaring a "new-type" (see page 6-20 of your manual). A "new-type" is incompatible with all other new-types. So, if you declare a procedure like this:

```
  PROCEDURE p( VAR s : STRING[10] ) ;
```

there is no way to pass another variable declared as STRING[10] to the procedure, since the two "STRING[10]" variables are different types! In order to pass a variable to the procedure, declare a type in the TYPE section like this:

```
  TYPE Str10 = STRING [ 10 ] ;
```

and declare the procedure like this:

```
  PROCEDURE p( VAR s : Str10 ) ;
```

Then, if you declare the string you want to pass as type Str10 as well, everything will work fine.

#36 - 515 chars 02/24/86 11:33:45
Re: To: Gary Cacace

We will soon have a file that demonstrates absolute memory access using PPascal. In the meantime, remember that you must be in supervisor mode if you want to access memory below $1000 or in the hardware. Also, in order to call assembly language routines, you declare them like this:

```
  PROCEDURE assem( -parameters- ) ;
    EXTERNAL ;
```

In your assembly language file, "assem" must be all capitals (ASSEM) and be declared to be ".globl". Your routine should also pull all parameters off the stack before returning!

#37 - 568 chars 02/24/86 11:37:10
Re: Libraries w/ Pascal

Several people have asked how to put Personal Pascal routines into a library (like PASGEM and PASLIB). If you want to do this, you must have the library manager AR68, available from Atari, not us. Make sure you get the patched version, or instructions on patching it, since it won't work unchanged. Also, you need the program FIXO to make your object files an even number of long-words in length. Your Pascal modules

should be compiled with the M+ and E+ options, and shouldn't reference any global variables, if you want any Pascal program to be able to use them

---

#40 - 358 chars 03/03/86 09:52:04
Re: Pascal Wishes

Several people have suggested that in a future update of Pascal we allow some of the Pascal program files to reside on a different disk (e.g., to put the compiler on a ramdisk). We have this on our wish-list for future versions. If any of you have other wishes for future Pascal versions, please leave a message here or write. Your thoughts are important.

#41 - 351 chars 03/03/86 09:56:22
Re: Problems with CASE in Pascal

Some people have had difficulty using the CASE statement with Pascal. So far, the problem has been that they tried to use a variable as a CASE constant. As the name implies the "tag-values" in a CASE statement MUST be constants! E.g., the following will generate an error:

```
  CASE i OF
  (* If x is a variable, error! *)
    x: do_something;
  END;
```

#42 - 216 chars 03/03/86 10:01:57
Re: Reading the cursor pos. on ST

Several people have asked how to read the cursor position from Personal Pascal (presumably in a TOS program). We will soon have a cursor movement support package available here which includes reading the cursor pos.

#43 - 216 chars 03/03/86 10:12:51
Re: Buffers and "rwabs"

If you want to pass the address of a
Pascal array as a buffer parameter to
the rwabs XBIOS call, pass the array
as a VAR parameter, and declare the
rwabs routine as taking a VAR param
of the type you gave the array.

I will not quote all the retoric about what the ST should have and about
upgrade paths....

I feel that the ST is quite a good deal and that is all it is. It is not
realistic to expect that it have SCSI, expandability, be compatable
forever, have unix, have a better keyboard, have built in 4 meg expandability,
plug in coprocessors, etc... Anyone who is involved in hardware development
where time and expense are major factors has to just be amazed that it exists
at all. It seems that an awful lot of good things are there and that if you
wanted all the feature that a more expensive computer affords then by all means
by a more expensive computer. In a computer selling for as little as the Atari
sells for *EVERY LITTLE BIT COUNTS*. a penny saved here and there will make
or break a cheap computer. In my opinion we have a lot to be happy about and
can certainly get around the limitations. Lets not use up the net bandwidth
by complaining about what could/should have been. Even though I would like
an expansion bus etc, Personnally, if it wasn't for the low price I would not
have anything at all...

We are working on a project to completely re-write the system documentation.
The writing should be complete by late Summer (this is a _big_ project).
Once done, we have a deal with a major book publisher to get this into
book form and into dealers and book sellers, a la the Commodore programmers
reference guide books. We should see this by the end of the year, but I
can't imagine how we could get it out sooner than that.

Keywords: Atari ST, 1 Megabyte, Bloody Resistors

Make sure you use heavy gauge wire (#22 or so) across the tops of the
RAM chips, and from the memory controller to the chips. Using something
like wire-wrap wire is not a good idea. Stretch the wires taut across the
tops of the chips and point-solder; don't leave any slack. (We've seen
upgrades with the wires kind of looped from one chip to the next. We don't
know /how/ they worked....)

Whether or not you need the resistors depends on the RAM chips and the
memory controller you've got. Some memory controllers have faster rise
and fall times, and generate undershoot which can fry the RAMs unless
they're protected by the resistors. The resistors should be placed close
to the memory controller (not near the RAM chips).

What on earth are you saying?

1. There is no "standard" xmodem utility on 4.2.

2. I have about 4 different xmodem utilities running on 4.2 on our
   VAX, and only 1 of them is called "umodem". The names of the others
   all can be traced to "xmodem" in their spelling.

3. The truth then is the following:
     On your machine someone has installed "umodem", a utility which
     provides xmodem file transfer (with a couple of goodies). On
     other machines this may not be the case: on another (4.2) system
     it may be called "xmodrec" and "xmodtran", or "sb" and "rb"...

4. For file transfer with the ST I find that "xmodrec" and "xmodtran"
   (posted to the net a while ago) work fine with "sttalk". I could send
   the programs to anyone who asks.

Boy mail really gets around. Ever since i mentioned the Professional GEM tutorial in one of the replies, my mailbox has been bombarded with requests (on last count 36 messages!). So here it is.

To get a nice print out of the tutorial you will need proff. So I am posting proff too. Proff will be posted in 4 parts. The tutorial itself will be posted in 6 parts (I am really asking for trouble with repost request :-). The easiest way to make everying will be to save the 4 parts of proff in one directory, and the 6 parts of the tutorial in another directory, then unshar all the files. To make proff read the file 'see.me' in the directory you save proff in. To make the tutorial see the file 'read.me' in the directory you save the tutorial in.

I realize some of you don't have the dev. system. Part 4 of the proff posting is a uuencoded version of proff.prg (you may need to rename it to proff.ttp), that has been wrapped in a shar script. When you unshar part4 of proff you will end up with a file called proff.uud. To get proff.prg run it through uudecode. In the instructions to make proff (the file 'see.me') i have also included instructions on how to make proff for a unix system. So you may if you prefer run the whole thing off on your unix host.

enjoy,

X * ltb.c - Lexical Table Builder
X *
X * Functional description:
X *
X *  This program builds a file containing the data
X *  structures of a compile-time-initialised hash table.
X *  This hash table may later be used for lexical analysis,
X *  where number of symbols to look up is sufficiently large
X *  to avoid a run-time table initialization.
X *  In order to guarantee the success of this setup, the
X *  hash routine, the lookup and install routines should be
X *  the same between ltb and the lexical analysis.
X *
X * synopsis:
X *
X *  ltb <input file> [table name]
X *
X * input file format:
X *
```

```
X *  <token>  <value identifier> [flag value]
X *
X *  token:        string of alphanumeric characters to be
X *                matched by the lexical analyser (no blanks).
X *           these token strings are "installed" to a hash
X *           table by ltb to avoid run-time overhead.
X *  value
X *  identifier:   A constant name to be used internally by the
X *           lexical analyser in place of the actual
X *           token value. a "#define <indentifier> <value>"
X *           is generated for each value identifier, where
X *           value is an odd and unique integer constant. If
X *           the value identifier is a `*' (star), then the
X *           previous value is repeated. Thus:
X *
X *                 token   ident.   flag
X *
X *                sp   SP   1
X *                space    *        { inherits SP  }
X *                blank    *        { inherits SP  }
X *                .    .    .
X *                .    .    .
X *
X *  flag value:   An additional integer field to pass flags etc. to
X *           the lexical analyser. If not specified, set to
X *           0. token value field must be present for this field
X *           to be obtained.
X *
X * outputs:
X *
X *  ltb generates two C include files:
X *
X *       [tablename].d:  compile time lexical constants (defines)
X *       [tablename].h:     initialised hash table.
X *
X *  where [tablename] is the name of the hash table as specified
X *  in the command line of ltb. If not specified, "lextab" is used
X *  as a default.
X *
X * routines used by LTB:
X *
X *  hash, lookup and a modified version of install routines,
X *  as defined in K&R, pp. 134 - 136.
X *
X * Application areas:
X *
X *  Lexical analysers for compilers, interpreters, spelling
X *  checkers.
X *
X * Author:
X *  Ozan S. Yigit
X *  Dept. of Computer Science
X *  York University

X.sect 0 1.0 Introduction
X This manual describes PROFF, a formatter based on the FORMAT utility
Xpresented in
X.ul
XSoftware Tools.
X PROFF was produced to provide a powerful formatter that can be used under
Xa variety of microcomputers, thus providing a consistent formatting tool
Xacross environments. PROFF can be used to format memos, reports, form letters
Xand
Xdocuments such as this manual. It can also be configured to mimic
Xother formatting
Xsystems of similar nature.
X This document itself was produced with PROFF, using most of its advanced
features.
XPROFF took care of such things as auto-paragraphing and the production of
Xthe Table of Contents as the manual was being formatted.
X PROFF was developed under a Digital Equipment Corporation Rainbow 100,
Xusing Mark Williams C Compiler for portability reasons. PROFF is
Xavailable under VAX/VMS operating system. PROFF implementations for
XIBM PC and APPLE ][ microcomputers are also underway.
X.st -14
XRainbow, VAX/VMS are trademarks of Digital Equipment Corporation.
X.br
XMark Williams C Compiler is a trademark of Mark Williams Company.
X.br
XIBM is a registered trademark of International Business Machines Inc.
X.br
XAPPLE is a trademark of Apple Computer Inc.
X.br
XUNIX is a trademark of Bell Laboratories.
X.bp
X.cl
X.sect 0 2.0 General Description
X.cl
X.sect 1 2.1 The Input
X The text that is to be formatted by PROFF is typed into an input file
Xusing any text editor. This file contains the text to be formatted
Xas well as PROFF commands.
X Each line in the input file is either a command line or a text line. A
Xcommand line is a line that begins with a period (".") . All other lines are
Xtext lines. The command lines are not printed - they tell PROFF how you want
```

```
Xit to format the text that follows. Appendix A summarizes all of the PROFF
Xcommands for a quick reference.
X.sect 2 2.1.1 Text
X Text can be entered into the input file in any format. PROFF removes all extra
Xblanks and tabs between words when operating in fill mode. This means you do
Xnot have to worry about how many words you put on a line, and you can break
Xlines wherever it is convenient to your typing. Note however, that you cannot
Xbreak a word between two lines.
X Blanks and tabs at the beginning of a line are not removed. This is useful
Xfor producing special tables and performing special types of indentation.
XThus, normal text lines should not have any leading tabs or blanks.
X.sect 2 2.1.2 Commands
X A command is a line that starts with a period. Immediately following the
Xperiod is a command name. Some commands accept a numeric quantity or a
Xcharacter string parameter, which must be separated from the command name
Xby a space or a comma. For example, an indent command might appear as follows:
X.save
X.in +5
X.nf
X.nj
X.sp
X|
X|It is to do nothing that the elect exists.
X|.in 5
X|- Oscar Wilde
X|
X.restore
X Assuming that the left margin was at column 1, PROFF would produce the
Xfollowing:
X.save
X.in +5
X.nf
X.nj
X.sp
X.need 4
X|
X|It is to do nothing that the elect exists.
X|     - Oscar Wilde
X|
X.restore
X.sp
X(In the examples above, as in those following, the vertical line indicates
Xthe left edge of input or the left edge of the printed page).
X The number following the command may be preceeded by a "+" or "-" sign.
XThis plus or minus sign indicates an addition or subtraction of the number
Xto or from the current value for the command. for example, the text:
X.sp
X.save
X.in +5
X.nf
X.nj
X.need 11
X|
```

```
X|Nothing to do but work,
X|.in +3
X|Nothing to eat but food,
X|.in -3
X|Nothing to wear but clothes
X|.in +3
X|To keep one from going nude.
X|.in +7
X|-Benjamin King
X|
X.in -5
X.sp
Xwill produce as output:
X.sp
X.in +5
X.need 6
X|
X|Nothing to do but work,
X|   Nothing to eat but food,
X|Nothing to wear but clothes
X|   To keep one from going nude.
X|          -Benjamin King
X|
X.restore
X If a number is not supplied with a command that requires a number, PROFF
Xwill use a default value. The defaults for each command are summarized in
XAppendix A.
X.cl
X.sect 1 2.2 The Output
X The main functions performed by PROFF are
X.ul
Xfilling
Xand
X.ul
Xjustifying.
XA line is
Xfilled by packing as many words onto it as will fit. The line is justified
Xby spacing words evenly between the left and right margins. When PROFF starts,
Xit assumes that the text is to be filled and justified. Of course, when fill
Xand justify are not needed (as in the case of a letter or a table), there are
Xcommands to turn these features off, and back on again, as necessary.
X When PROFF is in fill mode, it normally strips out extra spaces and tabs
Xbetween words.
X Many PROFF commands cause a
X.ul
Xbreak
Xto occur in the output. This means that the line currently being filled is
Ximmediately output. Any following text goes into a new output line.
X.cl
X.sect 1 2.3 Executing PROFF
X Once a text file is ready for formatting, PROFF is started by typing
Xthe program name, various options, name of the input file and the name
Xof the output file. For example the command
```

```
X.sp
X.in +5
XA> proff  -po5 proffman.prf proff.man
X.sp
X.in -5
Xwould produce this document as proff.man, from an input file proffman.prf,
Xshifted right by 5 spaces.
X(The symbol "A>" is CP/M system prompt).
X.cl
X.sect 1 2.4 Bibliographic Notes
X  PROFF wa produced by re-writing the Software Tools Formatter FORMAT.
XSome of the ideas are from Freshwater Institute RUNOFF, NROFF,
XUniversity of Waterloo SCRIPT
Xand other formatters of similar nature. The underlying ideas of the
Xmentioned above formatters may be found in
X.ul
XSoftware Tools
Xby B.W. Kernighan and P.J. Plauger. 1976. (Addison-Wesley, Reading, Mass.).

X.sect 0 3.0 Command Descriptions
X This section describes PROFF commands. Commands specify how the program is
Xto process the text lines in the input file. Lines in the input file that
Xbegin with a period (or the control character selected by the user)
Ximmediately followed by a command name are commands. Any line that begins
Xwith a period and followed by a _# or _! is a comment line and is ignored
Xby PROFF - this allows you to put information in the file that will be neither
Xprocessed nor output by PROFF.
X As described earlier, some of the commands can be followed by "parameters".
```

```
XParameters are used in executing a command; for example, in the command
X".sp 3", the parameter "3" tells the formatter to insert 3 blank lines into
Xthe document. The following conventions are used in describing the parameters:
X.sp
X.in +5
X.ti -2
Xo Parameters surrounded by square brackets are optional. If not supplied, PROFF
Xassumes a default value.
X.br
X(e.g. .sp [n])
X.sp
X.ti -2
Xo Parameters surrounded by angle brackets are mandatory. PROFF will display
Xa fatal error message if the parameter is absent. (e.g. .set <variable name>)
X.sp
X.ti -2
Xo Parameters surrounded by squiggly brackets are to be typed exactly as
Xindicated. (e.g. .pn {roman})
X.sp
X.ti -2
Xo A bar character seperating the parameters within brackets indicate an
Xalternative. (e.g. .st [+|-][n] means both .st [+n] and .st [-n])
X.in -5
X In describing the commands, the command is typed exacty as accepted by PROFF
Xwith the associated control character default ("."). If more than one form of
Xthe command is accepted by PROFF, the command names are separated with a
Xbar indicating an alternative.

X\! We use variables to avoid re-typing of multiple options over
```

```
X\! and over again. These variable names will be reused in the
X\! appendix to produce a quick referance
X\!
X\set FILL ".fi | .f | .fill"
X\comm FILL
XThe fill command causes a line to be filled with as many words as the right
Xmargin allows. For this purpose, all extra blanks and tabs are removed between
Xwords. Each word is separated with a single blank. PROFF automatically assumes
Xfill mode during the startup.
X\set NOFILL ".nf | .nofill"
X\comm NOFILL
XNo fill discontinues the filling of the text. PROFF simply copies the text
Xto the output. This command may be used to pass tables and other text
Xunaltered through the formatter.
X\set JUST ".ju | .j | .justify"
X\comm JUST
XJustify causes the words on a line to be evenly spaced between the left and
Xthe right margins. Note that lines can be justified only if lines are also
Xbeing filled. PROFF automatically assumes justify mode during the startup.
X\set NOJUST ".nj | .nojustify"
X\comm NOJUST
XNo justify discontinues the text justification.
X\in -5
X\cchar .
X.bp
X.cl
X.sect 1 3.2 Text Formatting
X.in +5
X.cchar \
X\set BREAK ".br | .break"
X\comm BREAK
XBreak causes a break: the current line is printed without justification,
Xand the next word is placed at the beginning of a new line. Note that many
XPROFF commands cause an implicit break.
X\set INDENT ".in | .lm | .leftmargin [+|-][n]"
X\comm INDENT
XIndent causes a break and indents the following lines [n] spaces to the
Xright of the left margin. [n] can be negative to allow beginning a line
Xto the left of the left margin, however, a line cannot begin to the left of
Xcolumn 0. If a plus or minus sign is used with n, then [n] is added or
Xsubtracted to or from the current value.
X\set TINDENT ".ti | .i | .left [+|-][n]"
X\comm TINDENT
XTemporary indent is identical to the indent command except that it
Xapplies only to the next line of printed text. Thus, the command
X".ti +5" would cause the next line to be printed 5 spaces to the right
Xof those that follow.
X\set SPACETO ".st | .spaceto [-][n]"
X\comm SPACETO
XSpaceto allows spacing to line [n] from the top of the current page.
XIf a negative [n] is specified, than spacing is performed to line [n]
Xfrom the bottom of the page (excluding the footer lines). Thus, footnotes
Xcan be set at a fixed distance from the bottom of the page by a command such
```

```
Xas ".st -5".
X\set SPACE ".sp | .s | .skip [n]"
X\comm SPACE
XSpace causes a break and skips [n] lines, except at the top of
Xa page. The space command
Xis dependent on the setting of line spacing.
X\set CENTER ".ce | .center [n | on | off]"
X\comm CENTER
XCenter causes the next [n] lines of text to be centered between the left
Xand right margins. Centering may be started with "on" and terminated with
X"off", in which case all input lines between these commands will be centered.
X\set UNDLINE ".ul | .underline [n | on | off]"
X\comm UNDLINE
XUnderline command causes the text on the next [n] input lines to be underlined
Xwhen printed. If [n] is omitted, only the next line is underlined. This command
Xdoes not cause a break, so words in filled text may be underlined by:
X\sp
X\save
X\cchar .
X.in +5
X.nf
X.need 11
X.sp
X|
X|The "Pay-off" Theory: Only
X|.ul

X|
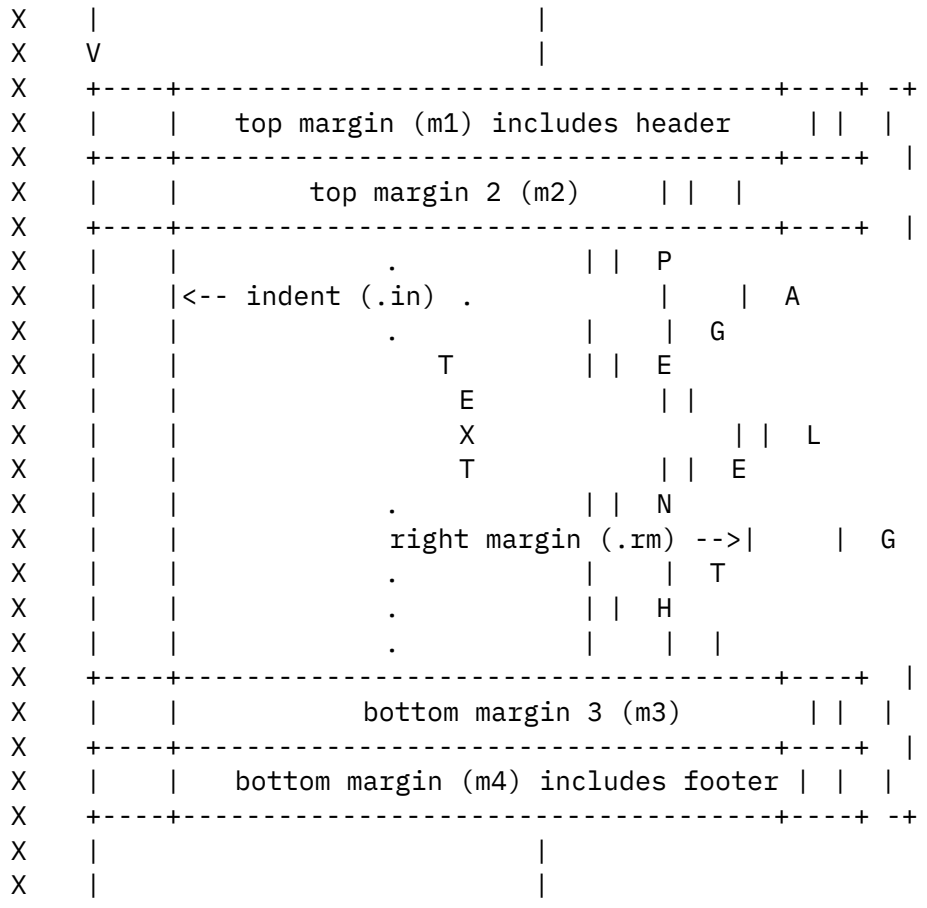
X.br
X|The "Pay-off" Theory: Only
X.ul
Xlosers
Xbelieve in
X.br
X|luck, horses, horoscopes and
X.ul
Xlotteries.
X.br
X|
X.sp
X.restore
XUnderlining may be started with "on" and terminated with "off", similar to
```

```
Xthe centering command.
X\set CUNDLINE ".ul | .underline [all | words]"
X\comm CUNDLINE
XThis version of the underline command is used to set the mode of
Xunderlining:
X\sp
X\nap
X\in +5
X\nf
Xall   - underline across all characters,
X        including spaces.
X\br
Xwords - underline words only
X\fi
X\sp
X\in -5
X\ap
X\set BOLD ".bd | .bold [n | on | off]"
X\comm BOLD
XThe bold command causes the text on the next [n] input lines to be highlighted
Xby overstriking. If [n] is omitted, only the next line is highlighted.
XBolding may be started with "on" and terminated with "off" as in the
Xcase of the center and underline commands.
X\set DBO ".db | .dbo | .disablebolding"
X\comm DBO
XTurns the bolding off, all bolding commands are ignored. This feature is
Xuseful for rough drafts.
X\set EBO ".eb | .ebo | .enablebolding"
X\comm EBO
XTurns the bolding feature back on. Bolding is turned on during the PROFF
Xstartup.
X\in -5
X\cchar .
X.bp
X.cl
X.sect 1 3.3 Page Formatting
X.in +5
X.cchar \
X\set LS ".ls | .spc | .spacing [n]"
X\comm LS
XLine spacing is the command to set line spacing. Set n to 1 for single spacing,
X2 for double spacing etc.
X\set BP ".bp | .pg | .page [n]"
X\comm BP
XThe begin page command causes a break, ends the current page, outputs
Xfooters if required and begins a new page. If [n] is present, the page number
Xis set to [n]. The default action is to number the pages incrementally.
X\set PN ".pn | .pagenumber {roman} | {arabic}"
X\comm PN
XPage number command defines the format of the page number. Uppercase roman
Xnumerals may be obtained with "roman" keyword. To convert the page numbers
Xback to normal, "arabic" is specified. PROFF uses arabic numerals as
Xa default.
```

```
X\set NPA ".np | .nopaging"
X\comm NPA
XNo paging disables the pagination. When PROFF is in no paging mode,
X"begin page" (.bp) and "page length" (.pl) commands are ignored. This mode
Xof operation is especially useful for using the proff output with the
Xmulti-column formatter (MC).
X\set PA ".pa | .paging"
X\comm PA
XPaging enables normal page generation. This command starts a
Xnew page and restores the page length to the
Xvalue previous to the ".np" command.
X\set NE ".ne | .need | .tp | .testpage [n]"
X\comm NE
XTest page checks to see whether at least [n] lines remain in the
Xcurrent page. If less than this number of lines remain, printing will resume
Xat the top of a new page. If [n] is missing, it is assumed to be zero.
X\set HE ".he | .header <text>"
X\comm HE
XHeader sets the text to be printed on top of each page. <text> is
Xdivided into sections which are to be left justified, centered and right
Xjustified. To divide <text> into these three parts, the first character is
Xassumed to be a separator. (e.g. /left/center/right/) But any non-alphanumeric
Xcharacter may also be used. The characters "#" and "%" are replaced with the
Xcurrent page number and day/time in the header.
X\set FO ".fo | .footer <text>"
X\comm FO
XFooter is identical to header except that it sets the text to be printed
Xat the bottom of each page.
X\set OHE ".oh <text>"
X\comm OHE
XThe odd header command sets the header for odd pages only.
X\set EHE ".eh <text>"
X\comm EHE
XThe even header command sets the header for even pages only.
X\set OFO ".of <text>"
X\comm OFO
XThe odd footer command sets the footer for odd pages only.
X\set EFO ".ef <text>"
X\comm EFO
XThe even footer command sets the footer for even pages only.
X\in -5
X\cchar .
X.bp
X.cl
X.sect 1 3.4 Page Layout
X.ap
X These commands are used to specify where on the page you want the formatted
Xtext to be placed. The general layout of a page is as follows:
X.nap
X.need 30
X.nf
X
X    page offset (.po)               |
```



```
X.fi
X.in +5
X.cchar \
X\set PO ".po | .offset [+|-][n]"
X\comm PO
XThe page offset command moves the entire page to the right or left depending on
the
Xspecified value. All indentation is according to the page offset. PROFF
Xassumes a page offset of 0 during the startup. If [n] is specified with a
Xplus or minus, it will be added or subtracted from the current value.
X\set RM ".rm | .rightmargin [+|-][n]"
X\comm RM
XRight Margin sets the position of the last printable character from the
Xleft edge of the page to [n]. Default value for right margin is 65.
XA plus or minus value will be added or subtracted from the current value.
XIf [n] is not specified, right margin is set to the default value.
X\set PL ".pl | .ps | .pagesize [n]"
X\comm PL
XPage length is used to set the number of lines that are to be printed
Xon a page including the header and footer lines. After [n] lines are printed,
Xthe paper will advance to the top of next page. The default page length is
X66 lines (11 inches for 6 lines/inch). This command is disabled if nopaging
Xis set.
X\set M1 ".m1 [n]"
X\comm M1
XMargin 1 sets the number of lines (including the header) which will be left at
Xthe top of the page to [n]. The default setting is 3. If [n] is omitted, is
```

```
Xset to the default.
X\set M2 ".m2 [n]"
X\comm M2
XMargin 2 sets the number of blank lines between the header and the first
Xline of text. The default setting is 2.
X\set M3 ".m3 [n]"
X\comm M3
XMargin 3 sets the number of blank lines between the footer and the last line
Xof text. The default setting is 2.
X\set M4 ".m4 [n]"
X\comm M4
XMargin 4 sets the number of lines (including the footer) which will be left at
Xthe bottom of the page to [n]. The default setting is 3.
X\in -5
X\cchar .
X.bp
X.cl
X.ap
X.sect 1 3.5 Table of Contents
X This section describes the the commands that are used to generate a table of
Xcontents. Basically, a contents line command is used in every place in
Xthe document where an entry is needed in the table of contents. PROFF
Xstores the text and the page number when it encounters this command.
XAfter the the body of the document is processed, a print contents command
Xdumps the contents table. The contents should be dumped in a new page, with
Xnofill. Page numbering should be disabled if the table of contents is to be
Xused in front of the document.
X.sp
X.in +5
X.ap
X.cchar \
X\set CL ".cl | .contline [<n> <text>]"
X\comm CL
XContents line specifies a line of <text> to be entered into the table of
Xcontents. <n> specifies the level at which the item is to be printed
Xin the table. When the table is printed, each level of entry will be
Xindented by specific number of spaces.
X<text> appears in the output exactly as it appears
Xin the contents line command, except that leading blanks are removed.
XIf no options specified in the contents line, a blank is inserted during
Xthe table output.
X\set PC ".pc | .printcont [n]"
X\comm PC
XPrint Contents causes the currently accumulated table of contents to be
Xprinted. If [n] is specified, it is used as the indent value for each
Xlevel.  If [n] is not specified, it is defaulted to 3.
X A contents line at level 0 is as wide as rightmargin-indent. The
Xoutlook of the table of contents may be changed by altering the right
Xmargin and indent values. A typical table of contents may be produced as
Xfollows:
X\in +5
X\nf

X.sect 1 3.6 Miscellaneous
X This section describes miscellaneous commands that radically increase the
Xformatting powers of PROFF. With the assistance of variables, PROFF can
Xgenerate form letters and documents with dynamic parts. The ability to save
Xand restore formatter context eliminates the need to remember the exact
Xsettings of the formatter across the document.
X.in +5
X.cchar \
X\set VSET ".vs | .set <variable> [definition]"
X\comm VSET
XSet variable  defines a variable to be later used in the document.
XIf the definition part is left out, PROFF uses the variable name as a prompt
Xand allows the user to define the variable interactively. Variable names cannot
Xstart with a numeric character, and may only contain alphanumeric
Xcharacters. The definition of a variable may not contain any blanks, unless
Xthey are surrounded by double-quotes. To get a double quote within a a quoted
Xdefinition, two double-quotes are used.
X Once the variable is
Xdefined, it can be used anywhere in the document, including the command
Xline itself. A variable substitution is invoked by a dollar sign (_$). (A
Xliteral _$ is inserted into text using ___$).
XA variable name must be delimited by a non-alphanumeric character within the
Xtext. If the contents of the variable is to be appended to other
Xalphanumeric characters, it must be surrounded by wiggly braces
X("{" and "}"). The following is an example of variable usage:
X\need 12
X\sp
X\nf
X|.nf
X|.vs v1 Murphy
```

```
X|_${v1}'s first law:
X|   Nothing is as easy as it looks.
X|_${v1}'s second law:
X|   Everything takes longer than you think.
X|Charley's observation:
X|   Computers were invented by _$v1.
X|
X\sp
XProduces the following:
X\sp
X\need 8
X|
X|Murphy's first law:
X|   Nothing is as easy as it looks.
X|Murphy's second law:
X|   Everything takes longer than you think.
X|Charley's observation:
X|   Computers were invented by Murphy.
X|
X\sp
X\fi
X\set VGET ".vg | .get <variable> <prompt>"
X\comm VGET
XGet variable is the interactive version of variable definition. In this
Xvariant, a prompt string is used to obtain the value of the variable,
Xwhich is typed at the user's terminal. If the prompt string is to
Xcontain blanks, tabs etc., it must be enclosed in double quotes. No quotes
Xare necessary for input text.
X\set VRG ".nr <a-z> [+|-][n]"
X\comm VRG
XNumber register is used to define registers that contain numeric values.
XThere are 26 number registers, named a-z. The command ".nr x n" sets the
Xnumber register "x" to value n; ".nr x +n" increments the number register
Xby n; ".nr x -n" decrements the number register by n. The value of the
Xnumber register x is placed in the text by the appearance of _@nx. A literal
X_@ may be inserted using ___@.
XNumber registers may be used on command lines and anywhere in the text.
X\set CCHAR ".cc | .cchar [char]"
X\comm CCHAR
XControl Character  sets the character that distinguishes PROFF
Xcommands from text to be formatted. As a default, control character is set to
X(".") period.
XThis character may be changed to something other than a period, either
Xto mimic other formatters or to disallow interpretation of lines beginning
Xwith a period. (This document makes heavy use of the .cc command).
X\set ECHAR ".ec | .echar [char]"
X\comm ECHAR
XEscape Character  sets the character that disallows the
Xinterpretation of spacial characters such as _@ and _$. PROFF uses an
Xunderline ("__") character as a default.
X\set SOU ".so | .source | .include | .require [filename]"
X\comm SOU
XThe source (include) command allows external files to be inserted into the
```

Xinput file
Xduring the formatting. Using this feature, tables, graphs and other
Xdocuments generated outside PROFF may be included into the document
Xbeing formatted. This feature is also very useful in including a common set
Xof macros during formatting. Include files may be nested inside other
Xinclude files. Currently, PROFF only allows a nested include
Xfiles level of 8. Filename may be enclosed in quotes.
X\set SAVE ".sv | .save"
X\comm SAVE
XThe save command allows the saving of the current formatter context on a
Xpushdown stack. The saved context of the formatter segment (FSECT) includes
Xthe following values and flags:
X\need 14
X\sp
X\nf
X\nap
Xvalues   flags   on | off
X------   -----
Xindent   (.in)   fill   (.fi | .nf)
Xright margin (.rm)   justify (.ju | .nj)
Xoffset   (.po)   paging   (.pa | .np)
Xline spacing (.ls)   number type   (.pn)
Xpage length (.pl)   bolding   (.eb | .db)
Xmargin values   (.m1)   autoparagraph (.ap | .na)
X   (.m2)
X   (.m3)
X   (.m4)
Xcontrol char (.cc)
Xescape char (.ec)
X\sp
X\ap
X\fi
X\set RST ".rs | .restore"
X\comm RST
XThe restore command pops the context stack and restores the values and flags
Xas defined above.
X\set LEX ".lx | .lex <command> [equate]"
X\comm LEX
XThe lexical modification command is essentially a permanent replacement of a
Xgiven command. This command is used for changing the command names without
Xresorting to the macro facility. Lex permanently removes the old
Xcommand name from command tables and replaces it with the new definition.
XIf the equate is not specified, the command becomes undefined and is
Xno longer recognised by PROFF. The command equate should not contain
Xnon-alphanumeric characters.
X\set APR ".ap | .autoparagraph"
X\comm APR
XThe autoparagraph command turns on the automatic paragraphing feature. If
Xauto-paragraphing is on, every line that starts with a
X\ul
Xblank
Xor a
X\ul

```
Xtab
Xcharacter starts a new paragraph. A new line is generated (.sp) and
Xthe beginning of the paragraph is indented by five spaces.
XAutoparagraphing is the equivalent of the following commands:
X\in +5
X\nf
X|
X|textextextextext
X|.sp
X|.ti +5
X|textextextextext
X|
X\in -5
X\fi
X\set NAP ".na | nap | .noautoparagraph"
X\comm NAP
XNo Autoparagraph command disables auto-paragraphing.
X\set WRT ".wr | .write <string>"
X\comm WRT
XWrite is a special output command, only to be used to configure printers
Xand other output devices with escape sequences. This command outputs the
Xassociated string as it is encountered, without going through the normal
Xoutput routines of the formatter. Currently, the output string may contain
Xcontrol characters specified as "^<char>", decimal numbers within the range
Xof 1-255, and other characters. Blanks within the string are skipped. Any
Xportion of the string enclosed with double quotes is output as is. To output
Xa double quote, two double quotes must be used within the quoted string.
XFollowing is a typical string to set a Digital La-100 printer to letter
Xquality print mode:
X\sp
X\nf
X\in +5
X|
X|.wr ^["[2z"
X|
X\sp
X\fi
X\in -5
XIn the control string, "^[" is the ASCII equivalent of the Escape (esc)
character.
XFollowing mapping table is used to convert characters starting with a caret
Xto their binary equivalents: ("|" indicates an alternative)
X\nf
X\nap
X\sp
X\in +5
XControl chr  Dec. Oct. Hex.

X.cl
X.sect 1 3.7 Defining New Commands (Macros)
X In document formatting, it is common to repeat a series of commands at
Xseveral places in the document. PROFF allows you to define a new command
Xthat will replace these repeated commands. This not only saves typing but
Xensures that
X.ul
Xexactly
Xthe same sequence of commands are applied throughout the document. A new
Xcommand that you define is formally called a
X.ul
Xmacro.
XTo define a macro, you must use the define macro (.de | .define) and
Xend macro (.en) commands.
X.in +5
X.cchar \
X\set DEF ".de | .define <macro name>"
X\comm DEF
XDefine is used to define a <macro name> to which a series of commands to
Xbe assigned. This definition line is followed by any number of PROFF
```

```
Xcommands and/or text which define the action that the macro
Xwill subsequently produce. Macros may refer to other macros.
X\set ENM ".en"
X\comm ENM
XEnd macro is the last line in the command definition. You must put in this
Xcommand to finish a currently defined macro. ".en" command should not be
Xre-defined as a macro.
X\in -5
X\sp
XThe example below defines macros ".note" and ".endnote", similar to the
XRUNOFF commands of the same name.
X\in +5
X\nap
X\nf
X\need 20
X\sp
X|
X|.define note
X|.sp
X|.ce
X|NOTE
X|.sp
X|.fi
X|.in +5
X|.rm -5
X|.en
X|
X|.define endnote
X|.sp
X|.nf
X|.in -5
X|.rm +5
X|.en
X|
X\in -5
X\ap
X\fi
X A macro is used like any other PROFF command, control character followed
Ximmediately  by the name of the macro. For example, the above macros
Xmay be used as follows:
X\in +5
X\nap
X\need 9
X\nf
X\sp
X|
X|.note
X|textextextextextextextextextext
X|              .
X|          .
X|          .
X|.endnote
X|
```

```
X\in -5
X\sp
X\fi
XThe following note is generated by the same macros described previously.
X\cc .
X.nap
X.note
XFlap's Law: Any inanimate object, regardless of its position or configuration,
Xmay be expected to perform at any time in a totally unexpected manner for
Xreasons that are either entirely obscure or else completely mysterious.
X.endnote
X.fi
X.cc \
X\ap
XSpecial symbols may be used within a macro definition. These symbols represent
Xthe parameters passed to a macro, delimited by blanks or commas.
XThese symbols are _$0 for macro name, _$1 for the first parameter, _$2 for
Xthe second parameter and so on, up to _$9 for the ninth parameter. Currently,
Xmacro parameters may only contain alphanumerics, no string parameters are
Xpossible. The previous macro "note" may now be defined as follows:
X\in +5
X\nap
X\nf
X\need 20
X\sp
X|
X|.define note
X|.sp
X|.ce
X|_$2 _$3 _$4 _$5 _$6 _$7 _$8 _$9
X|.nr m _$1
X|.sp
X|.fi
X|.in +_$1
X|.rm -_$1
X|.en
X|
X|.define endnote
X|.sp
X|.nf
X|.in -_@nm
X|.rm +_@nm
X|.en
X|
X\in -5
X\ap
X\fi
X In this version of the "note" and "endnote" macros, the first parameter (_$1)
Xis used to pass the value for indentation and right margin adjustment.
XAll the rest of the macro parameters (_$2 - _$9) are used as the title of
Xthe note. The indent value passed as the first parameter is also saved in the
Xnumber register "m" to communicate it to the "endnote" macro, such that
Xwhen the endnote macro is called, both indent and right margin values are
```

```
Xadjusted back to normal. It is possible and may be more useful to use
X".save" and ".restore" commands to accomplish the same task, especially if
Xthe macro alters the current formatting context drastically. The ".note"
Xand ".endnote" macros may be called as follows:
X\in +5
X\nap
X\need 9
X\nf
X\sp
X|
X|.note 5 Asimov's Law of Robotics
X|textextextextextextextextextext
X|               .
X|          .
X|          .
X|.endnote
X|
X\in -5
X\fi
X\ap
X In this usage, the indent value will be adjusted by +5, right margin will
Xbe adjusted by -5, and the title "Asimov's Law of Robotics" will appear
Xcentered above the note.
X\cchar .
X.bp
X.cl
X.sect 0 4.0 Executing PROFF
X The PROFF program  may be invoked with a series of optional parameters and
Xfilenames on the command line. The command synopsis is:
X
XPROFF [+n] [-n] [-v] [-s] [-pon] [-ifile] input [output]
X
XThe square brackets indicate an optional parameter. Interpretation of the
Xparameters is as follows:
X.nap
X.in +10
X.define opt
X.need 5
X.sp
X.ti -5
X.bd
X$1
X.br
X.en
X.opt +n
XStart the printing of the document at the first page with
Xnumber n.
X.opt -n
XStop printing at the first page numbered higher than n.
X.opt -v
XVerbose mode. PROFF indicates the source files being included into
Xdocument, and produces a summary of the number of textlines read in, the number
Xof lines and actual pages generated. A memory usage summary of internal
```

```
Xstorage for macros, stacks and tables is also displayed.
X.opt -s
XStop before each page, including the first one to allow paper
Xadjustment. A prompt is given just before the first page. For each
Xpage thereafter, the terminal bell is rung to indicate that another sheet
Xof paper is needed.
X.opt -pon
XSets the page offset to n. This is equivalent to ".po" command within
Xthe document. It is recommended that -pon option be used instead of
Xembedding the offset value within the document.
X.opt -ifile
XIncludes the given file to the formatted document. This is equivalent to
Xa ".include file" command within the document. This option may be
Xrepeated more than once, -ifile1 -ifile2 etc.
X.opt input
XSpecifies the input file to be formatted. PROFF does not impose any
Xfile extension. The recommended extension is ".PRF".
X.opt output
XSpecifies the output file for the formatted document. If this is omitted,
Xoutput is directed to the user's terminal.
X.in -10
X
XFollowing are some examples of PROFF command lines:
X
X.ti +5
XA>PROFF -v proffman.prf
X
XFormat this document (proffman.prf) in verbose mode, and output the
Xformatted document to the
Xterminal.
X
X.ti +5
XA>PROFF +5 -imacros.pma proffman.prf
X
XFormat this document, include the external file MACROS.PMA, skip the first
Xfour pages and output the formatted document to the terminal.
X
X.ti +5
XA>PROFF -po10 proffman.prf proff.man
X
XFormat this document, shift the entire document by 10 spaces to right and
Xoutput to a file called proff.man.
X.bp
X.cl
X.sect 0 5.0 Tips on using PROFF
X.ap
X.sect 1 5.1 Care and Feeding of Memory
X PROFF uses a dynamic memory allocation scheme for some of its operations.
XThese are macro definitions, contents lines, variables and save context
Xoperation.
XRunning PROFF under microcomputers with limited memory resources (64k or less)
Xrequire some care in using these commands:
X.list 3
```

```
X.item a)
XDo not declare macros that are not needed within the document.
X.item b)
XDo not use comments within macros. Due to delayed evaluation, comments
Xwill also be stored as a part of the macro definition.
X.item c)
XWhere possible, avoid using too much text within macros. It is just as
Xeasy to pass the information during the macro call.
X.item d)
XUse only the shortest form of commands within macros.
X.item e)
XBe brief in contents line text.
X.item f)
XUse short variable names as long as it is not so cryptic as to be confusing.
X.item g)
XAvoid unnecessary blanks within the variable definitions.
X.item h)
XAvoid too many context saves without a corresponding restore. The restore
Xoperation reclaims the memory used for a save.
X.nolist
X Even if the formatter is used with a system of large memory resources,
Xsome of the precautions above are applicable. (Utz's 4th law of Computer
XProgramming: Any given program will eventually expand to fill all the
Xavailable memory.) Using the -v option under memory-restricted systems
Xmay be useful in determining the memory usage.
X
X.sect 1 5.2 Formatting without fuss
X PROFF, using its default settings, may provide reasonably formatted output
Xin many situations.
XAs an example, examine the document PROFF.TUT. This document does not use
XANY formatting commands. All formatting is done with the default settings.
X
X.sect 1 5.3 Variables within macros
X Variable expansions may be performed within the macros. Typically, one
Xof the parameters of the macro is assumed to be a variable, which is expanded
Xonly after the macro is used. Thus:
X.in +5
X.nf
X
X|
X|.define xx
X|.ce
X|_$_$1
X|.cl _$_$1
X|.en
X|
X
X.in -5
X.fi
XThe macro xx assumes the first parameter to be a variable, which is
Xcentered on the page, and also entered in the table of contents.
XNote the usage of "_$_$1". The lines within a macro are scanned from
Xright to left for parameter expansion. Thus, "_$1" is expanded first,
```

```
Xresulting in "_$<first parameter>". This is later expanded as a variable.
X
X.bp
X.cl
X.sect 0 6.0 Example macros
X
X.nf
X.in +5
X.cc \
X.!
X.! macros to create a point-form lists.
X.! note the use of number registers within
X.! the macros.
X.!------------
X.define list
X.nr a _$1
X.in _$1
X.en
X.!------------
X.define item
X.sp
X.ti -_@na
X_$1
X.en
X.!------------
X.define nolist
X.in -_@na
X.sp
X.en
X.!------------
X
X\in -5
X\fi
XThe "list" macro is used to generate point-form lists. The first parameter
Xis an indent value, size of point-str + 1. A typical usage may be as
Xfollows:
X\need 16
X\in +5
X
X\nf
X|
X|Project work involves:
X|.sp
X|.list 3     { size-of-point-str + 1 }
X|.item a)         { "a)" is the point-str }
X|choosing a topic
X|.item b)
X|defining the topic
X|.item c)
X|research
X|.item d)
X|organizing the notes
X|{etc.}
```

```
X|.nolist     { readjusts the indent  }
X|
X\in -5
X
XThe above usage will produce the following:
X\need 12
X\in +5
X
X|
X|Project work involves:
X|
X|a) choosing a topic
X|
X|b) defining the topic
X|
X|c) research
X|
X|d) organizing the notes
X|
X
X\in -5
X\fi
XThe point-form recommendations under section 5.1 (Care and Feeding of
XMemory) were generated with the same set of macros described above.
X\cc .

XProff - A portable formatter
X
XThis is the first distribution of PROFF, a formatter based
Xon software tools ROFF. It is mainly a C re-write of ROFF,
X(now known as FORMAT), with some expansions. It is mainly
Xintended for non-UN*X systems, CP/M, MS-DOS and the like.
X
XProff was originally written for The Faculty of Administrative
XStudies, York University, tto supplement their microcomputer
Xenvironment. As of this release, the formatter is in the
Xcontrol of The Faculty of Administrative Studies.
X
XThere is no man page for proff, for it was never intended
Xfor UN*X systems. There is, however two comprehensive
Xdocuments to answer all questions.
X
XThe C code for PROFF is quite warped, and should be approached
Xcarefully. [Ok..Ok.. it is all my fault.. too much midnight
Xoil..]  It is reasonably customazible, by changing proffsym.new.
XThis file is processed by ltb, a static hash table generator.
XThis approach is most useful to change the operator keywords,
Xcreate aliases, and it also bypassess the initialization
Xoverhead. [see the makefile for the right output file names
Xfor ltb]
X
XPROFF is not copyrighted, at least for this release. Future
Xreleases may contain York University copyright.
```

```
X
XPlease send me all updates, bugfixes and other tidbits,
Xso that future releases may be coordinated smoothly.
X
Xenjoy.

X    After capturing and unshar'ing all the parts of this proff
Xposting you should end up with the following files:
X
Xproff.uud             lookup.h  proff.c       putwrd.c
Xdebug.h      lextab.d  ltb.c         proff.h       pxlex.c
Xdecl.h       lextab.h  make.sh       proff01.c pxxparse.c
Xdefs.h       lnk       makefile  proff02.c read.me
Xdostuff2.c   look.c        map.c         proffman.prf  see.me
Xeval.c       lookup.c  pinit.c       proffsym.new  stack.c
X
XThis file is see.me
X
XHow to make proff on the ST:
X
X    1) You will have to edit stdio.h supplied with the dev. system
Xto include the following lines at the bottom of stdio.h.
X
X    #ifdef DECL
X    #include <decl.h>
X    #endif
X
X    We do this so that when the pre-processor symbol DECL is
Xdefined the file decl.h gets included, and if it isn't then stdio.h
Xlooks exactly like it did before we added the lines. In decl.h we
Xdeclare all the commonly used function in C that do not returns the
Xtype int. This a important as in the Alcyon C compiler
X sizeof(int) != sizeof(int *). You may if you like include decl.h
Xelsewhere, but you will have to ensure that each of the modules
X(source files) has decl.h included. We found it convenient to put it
Xin stdio.h as above.
```

```
X
X    2) For those of you who have Micro C Shell and CC that i had
Xposted earlier to this newgroup, you can simply hit
X
X    make
X
Xat the Micro C Shell prompt.
X
X    3) For those who don't have Micro C Shell, but have CC, see
Xthe file make.sh, and enter those commands.
X
X    4) For those who don't have either, you will have to see
Xmake.sh and compile each C file such that DECL is defined, so you may
Xhave to  change your normal batch file somewhat to have the
Xpreprocessor switch in there to define the symbol DECL.
X
XPlease note that make.sh was set up to have all the sources, objects
Xetc in the current directory. If you are compiling on floppies you may
Xhave to  change that.
X
XThe file lnk contains the list of files to be linked, and is used with
Xlink68 as follows
X
X    link68 [com[lnk]]
X    relmod proff
X
XThe above process should yield proff.prg. If you want to use it from
Xthe desktop, rename it to proff.ttp.
X
X
XMaking Proff on the Vax
X    Simply hit
X    make
X
XMaking the users guide
X    On either the St or Vax hitting
X
X    proff -po8 proffman.prf proff.man
X
X    Will result in proff.man. (You may want to play with -po<n> to
Xget the correct left margin spacing for your printer).
X
X    If you have any problems/suggestions i may be reached at the
Xfollowing addresses:

Upon unshar'ing this part you will get proff.uud. Run proff.uud
through uudecode to get proff.prg

----------------------cut here---------------------------------
```

X.PART I Windows
X.SH IN THE BEGINNING
XIn GEM, creating a window and displaying it are two different functions. The
Xcreation function is called wind_create, and its calling sequence is:
X.FB wind_create()
Xhandle = wind_create(parts, xfull, yfull, wfull, hfull);
X.FE
XThis function asks GEM to reserve space in its memory for a new window
Xdescription, and to return a code or "handle" which you can use to refer to the
Xwindow in the future. Valid window handles are positive integers; they are not
Xmemory pointers.
X.PP
XGEM can run out of window handles. If it does so, the value returned is
Xnegative. Your code should always check for this situation and ask the
Xprogram's user to close some windows and retry if possible. Handle zero is
Xspecial. It refers to the "desktop", which is predefined as light green (or
Xgray) on the ST. Window zero is always present and may be used, but never
Xdeleted, by the programmer.
X.PP
XThe xfull, yfull, wfull, and hfull parameters are integers which determine
Xthe maximum size of the window. Xfull and yfull define the upper left corner of
Xthe window, and wfull and hfull specify its width and height. (Note that all of
Xthe window coordinates which we use are in pixel units.)
X.PP
XGEM saves these values so that the program can get them later when processing
XFULL requests. Usually the best maximum size for a window is the entire
Xdesktop area, excepting the menu bar. You can find this by asking wind_get for
Xthe working area of the desktop (handle zero, remember):
X.FB wind_get()
Xwind_get(0, WF_WXYWH, &xfull, &yfull, &wfull, &hfull);
X.FE
XNote that WF_WXYWH, and all of the other mnemonics used in this article, are
Xdefined in the GEMDEFS.H file in the ST Toolkit.
X.PP
XThe parts parameter of wind_create defines what features will be included in
Xthe window when it is drawn. It is a word of single bit flags which indicate
Xthe presence/absence of each feature. To request multiple features, the flags
Xare "or-ed" together. The flags' mnemonics and meanings are:
X.BO
XNAME - A one character high title bar at the top of the window.
X.EO
X.BO
XINFO - A second character line below the NAME.
X.EO
X.BO
XMOVER - This lets the user move the window around by "dragging" in the NAME
Xarea. NAME also needs to be defined.
X.EO
X.BO
XCLOSER - A square box at the upper left. Clicking this control point asks
Xthat the window be removed from the screen.

```
X.EO
X.BO
XFULLER - A diamond at upper right.  Clicking this control point requests
Xthat the window grow to its maximum size, or  shrink back down if it is already
Xbig.
X.EO
X.BO
XSIZER - An arrow at bottom right.  Dragging the SIZER lets  the user choose
Xa new size for the window.
X.EO
X.BO
XVSLIDE - defines a right-hand scroll box and bar for the window. By dragging
Xthe scroll bar, the user requests that the  window's "viewport" into the
Xinformation be moved.   Clicking on the gray box above the bar requests that
Xthe window be moved up one "page". Clicking below the  bar requests a down page
Xmovement.  You have to define  what constitutes a page or line in the
Xcontext of your application.
X.EO
X.BO
XUPARROW - An arrow above the right scroll bar.  Clicking here requests that
Xthe window be moved up one "line".  Sliders and arrows almost always appear
Xtogether.
X.EO
X.BO
XDNARROW - An arrow below the right scroll bar.  Requests that  window be
Xmoved down a line.
X.EO
X.BO
XHSLIDE - These features are the horizontal equivalent of the RTARROW
Xabove.  They appear at the bottom of the window.  Arrows LFARROW  usually
Xindicate "character" sized movement left and right. "Page" sized
Xmovement has to be defined by each application.
X.EO
X.PP
XIt is important to understand the correspondence between window features and
Xevent messages which are sent to the application by the GEM window manager.  If
Xa feature is not included in a window's creation,  the user cannot perform the
Xcorresponding action, and your application will  never receive the matching
Xmessage type.  For example, a window without a  MOVER may not be dragged by the
Xuser, and your app will never get a WM_MOVED  message for that window.
X.PP
XAnother important principle is that the application itself is responsible for
Ximplementing the user's window action request when a message is received.  This
Xgives the application a chance to accept, modify, or reject the user's request.
X.PP
XAs an example, if a WM_MOVED message is received, it indicates that the user
Xhas dragged the window.  You might want to byte or word align the requested
Xposition before proceeding to move the window. The wind_set calls used to
Xperform the actual movements will be described in the next article.
X.SH OPEN, SESAME!
XThe wind_open call is used to actually make the window appear
Xon the screen.  It animates a "zoom box" on the screen and then draws in the
Xwindow's frame.  The calling sequence is:
```

X.FB wind_open()
Xwind_open(handle, x, y, w, h);
X.FE
XThe handle is the one returned by wind_create. Parameters x, y, w, and h
Xdefine the initial location and size of the window. Note that these
Xmeasurements INCLUDE all of the window frame parts which you have requested. To
Xfind out the size of the area inside the frame, you can use
X.FB wind_get()
Xwind_get(handle, WF_WXYWH, &inner_x, &inner_y, &inner_w, &inner_h);
X.FE
XWhatever size you choose for the window display, it cannot be any larger than
Xthe full size declared in wind_create.
X.PP
XHere is a good place to take note of a useful utility for calculating window
Xsizes. If you know the "parts list" for a window, and its inner or outer size,
Xyou can find the other size with the wind_calc call:
X.FB wind_calc()
Xwind_calc(parts, kind, input_x, input_y, input_w, input_h, &output_x,
X&output_y, &output_w, &output_h);
X.FE
XKind is set to zero if the input coordinates are the inner area, and you are
Xcalculating the outer size. Kind is one if the inputs are the outer size and
Xyou want the equivalent inner size. Parts are just the same as in wind_create.
X.PP
XThere is one common bug in using wind_open. If the NAME feature is
Xspecified, then the window title must be initialized BEFORE opening the window:
X.FB wind_set()
Xwind_set(handle, WF_NAME, ADDR(title), 0, 0);
X.FE
XIf you don't do this, you may get gibberish in the NAME area or the system
Xmay crash.   Likewise, if you have specified the INFO feature, you must make a
Xwind_set call for WF_INFO before opening the window.
X.PP
XNote that ADDR() specifies the 32-bit address of title. This expression is
Xportable to other (Intel-based) GEM systems. If you don't care about
Xportability, then &title[0], or just title alone will work fine on the ST.
X.SH CLEANING UP
XWhen you are done with a window, it should be closed and
Xdeleted. The call
X.FB wind_close()
Xwind_close(handle);
X.FE
Xtakes the window off the screen, redraws the desktop underneath it,
Xand animates a "zoom down" box. It doesn't delete the window's
Xdefinition, so you can reopen it later.
X.PP
XDeleting the window removes its definition from the system, and makes that
Xhandle available for reuse. Always close windows before deleting, or you may
Xleave a "dead" picture on the screen. Also be sure to delete all of your
Xwindows before ending the program, or your app may "eat" window handles. The
Xsyntax for deleting a window is:
X.FB wind_delete()
Xwind_delete(handle);

X.FE
X.SH THOSE FAT SLIDERS
XOne of ST GEM's unique features is the proportional
Xslider bar. Unlike other windowing systems, this type of bar gives visual
Xfeedback on the fraction of a document which is being viewed, as well as the
Xposition within the document. The catch, of course, is that you have two
Xvariables to maintain for each scroll bar: size and position.
X.PP
XBoth bar size and position range from 1 to 1000. A bar size of 1000 fills
Xthe slide box, and a value of one gets the minimum bar size. To compute the
Xproper size, you can use the formula:
X.br
X.sp 1
X.ce 1
Xsize = min(1000, 1000 * seen_doc / total_doc)
X.br
X.sp 1
XSeen_doc and total_doc are the visible and total size of the document
Xrespectively, in whatever units are appropriate. As an example, if your window
Xcould show 20 lines of a 100 line text file, you should set a slider size of
X200. Since the window might be bigger than the total document at some points,
Xyou need the maximum function.   If the document size is zero, force the slider
Xsize to 1000. (Note: You will probably need to do the computation above with
X32-bit arithmetic to avoid overflow problems).
X.PP
XOnce you have computed the size, use the wind_set function to configure the
Xscroll bar:
X.FB wind_set()
Xwind_set(handle, WF_VSLSIZE, size, 0, 0, 0);
X.FE
XThis call sets the vertical (right hand) scroll bar. Use WF_HSLSIZE for the
Xhorizontal scroller. All of these examples are done for the vertical
Xdimension, but the principles are identical in the other direction.
X.PP
XBar positioning is a little tougher.   The most confusing aspect is that the
X1-1000 range does not set an absolute position of the bar within the
Xscroll box. Instead, it positions the TOP of the bar within its
Xpossible range of variation.
X.PP
XLet's look at our text file example again to make this clearer. If there are
Xalways 20 lines of a 100 line file visible, then the top of the window must be
Xalways be somewhere between line 1 and line 81. This 80 line range is
Xthe actual freedom of movement of the window. So, if the window were
Xactually positioned with its top at line 61, it would be at the
Xthree-quarter position within the range, and we should set a scroll
Xbar position of 750. The actual formula for computing the position is:
X.sp 1
X.ce 1
Xpos = 1000 * (top_wind - top_doc) / (total_doc - seen_doc)
X.sp 1
XTop_wind and top_doc are the top line in the current window and the whole
Xdocument, respectively. Obviously, if seen_doc is greater or equal to
Xtotal_doc, you need to force a zero value for pos. This calculation may seem

```
Xrather convoluted the first time through, but is easy once you have done it.
XWhen you have computed the position, wind_set configures the scroll bar:
X.FB wind_set()
Xwind_set(handle, WF_VSLIDE, pos, 0, 0, 0);
X.FE
X.sp 1
X.ce 1
XWF_HSLIDE is the equivalent for horizontal scrolling.
X.sp 1
XIt is a good practice to avoid setting the slider size or position if they
Xare already at the value which you need.  This avoids an annoying redraw flash
Xon the screen when it is not necessary.  You can check on the current
Xvalue of a slider parameter with wind_get:
X.FB wind_get()
Xwind_get(handle, WF_VSLIDE, &curr_value, &foo, &foo, &foo);
X.FE
XFoo is a dummy variable which needs to be there, but is not used. Substitute
XWF_VSLIDE with whatever parameter you are checking.
X.PP
XOne philosophical note on the use of sliders:  It is probably best to avoid
Xthe use of both sliders at once unless it is clearly appropriate to the type of
Xdata which is being viewed.
X.PP
XSince Write and Paint programs make use of the sheet-of-paper metaphor,
Xmoving the window around in both dimensions is reasonable. However, if the data
Xis more randomly organized, such as a tableau of icons, then it is probably
Xbetter to only scroll in  the vertical dimension and "reshuffle" if
Xthe window's width is changed. Then the user only needs to manipulate
Xone control to find information which is off-screen.  Anyone who has
Xhad trouble finding a file or folder within a Desktop window will
Xrecognize this problem.
X.SH COMING UP NEXT
XIn my next column in Antic Online, we'll conclude the tour of the ST's
Xwindowing system.  I'll discuss the correct way to redraw a window's contents,
Xand how to handle the various messages which an application receives from the
Xwindow manager.  Finally, we'll look at a way to redesign the desktop
Xbackground to your own specifications.
X.SH FEEDBACK
XOne of the beauties of an on-line column is that you can make your comments
Xknown immediately.  To register your opinions, select ST FEEDBACK, enter your
Xmessage, leave your name, and enter a blank line to exit.
X.PP
XI am interested in hearing proposals for topics, feedback on the technical
Xlevel of the column, and reports on bugs and other "features" in both
Xthe column and the ST itself.  Your comments will be read by the ANTIC
Xstaff and myself and, though we might not answer individual questions,
Xthey will be used to steer the course of future columns.

X.PART II Windows
X.SH EXCELSIOR
XIn this installment, we continue the exploration of GEM's window manager by
Xfinding out how to process the messages received by an application
Xwhen it has a window defined on the screen.
X.PP
XAlso, beginning with this column, sample C code demonstrating the techniques
Xdiscussed will be available on SIG*ATARI in DL5.  This will allow you to
Xdownload the code without interference by the CIS text-formatter used by ANTIC
XONLINE output.
X.PP
XThe file for this column is GEMCL2.XMO.  All references  to non-GEM routines in
Xthis column refer to this file.  Please note that  these files will not contain
Xentire programs.  Instead, they consist of small pieces of utility code which
Xyou may copy and modify in your own  programs.
X.SH REDRAWING WINDOWS
XOne of the most misunderstood parts of GEM is the correct method for drawing
```

Xwithin a window. Most requests for redrawing are generated by the GEM system,
Xand arrive as messages (read with evnt_multi) which contain the handle of the
Xwindow, and the screen rectangle which is "dirty" and needs to be redrawn.
X.PP
XScreen areas may become dirty as a result of windows being closed, sized down,
Xor moved, thus "exposing" an area underneath. The completion of a dialog, or
Xclosing of a desk accessory may also free up a screen area which needs to be
Xredrawn. When GEM detects the presence of a dirty rectangle, it checks its
Xlist of open windows, and sends the application a redraw message for each of
Xits windows which intersects the dirty area.
X.SH CAVEAT EMPTOR
XGEM does not "clip" the rectangle which it sends to the application; that is,
Xthe rectangle may not lie entirely within the portion of the window which is
Xexposed on the screen. It is the job of the application to determine in what
Xportion of the rectangle it may safely draw.   This is done by examining the
X"rectangle list" associated with the window.
X.PP
XA rectangle list is maintained by GEM for each active window. It contains the
Xportions of the window's interior which are exposed, i.e., topmost, on the
Xscreen and within which the app may draw.
X.PP
XLet's consider an example to make this clear. Suppose an app has opened two
Xwindows, and there are no desk accessory windows open. The window which is
Xtopmost will always have only one rectangle in its list. If the two are
Xseparate on the screen, then the second window will also have one rectangle.
XIf they overlap, then the top window will "break" the rectangle of the bottom
Xone. If the overlap is at a corner, two rectangles will be generated for the
Xbottom window. If the overlap is on a side only, then three rectangles are
Xrequired to cover the exposed portion of the bottom window. Finally, if the
Xfirst window is entirely within the second, it requires four rectangles in the
Xlist to tile the second window.
X.PP
XTry working out a few rectangle examples with pencil and paper to get the feel
Xof it. You will see that the possible combinations with more than two windows
Xare enormous. This, by the way, is the reason that GEM does not send one
Xmessage for each rectangle on the list: With multiple windows, the number of
Xmessages generated would quickly fill up the application's message queue.
X.PP
XFinally, note that every app MUST use this method, even if it only
Xuses a single window, because there may be desk accessories with their
Xown windows in the system at the same time. If you do not use the
Xrectangle lists, you may overwrite an accessory's window.
X.SH INTO THE BITS
XFirst, we should note that the message type for a redraw request is WM_REDRAW,
Xwhich is stored in msg[0], the first location of the message returned by
Xevnt_multi. The window handle is stored in msg[3]. These locations are the
Xsame for all of the message types being discuss. The rectangle which needs to
Xbe redrawn is stored in msg[4] through msg[7].
X.PP
XNow let's examine the sample redraw code in more detail. The redraw loop is
Xbracketed with mouse off and mouse on calls. If you forget to do this, the
Xmouse pointer will be over-written if it is within the window and the next
Xmovement of the mouse will leave a rectangular blotch on the screen as a piece

Xof the "old" screen is incorrectly restored.
X.PP
XThe other necessary step is to set the window update flag. This prevents the Xmenu manager from dropping a menu on top of the screen portion being redrawn. XYou must release this flag at the end of the redraw, or the you will be unable Xto use any menus afterwards.
X.PP
XThe window rectangles are retrieved using a get-first, get-next scheme which Xwill be familiar if you have used the GEM DOS or PC-DOS wildcard file calls. XThe end of the rectangle list has been reached when both the width and height Xreturned are zero. Since some part of a window might be off-screen X(unless you have clamped its position - see below), the retrieved Xrectangle is intersected with the desktop's area, and then with the Xscreen area for which a redraw was requested.
X.PP
XNow you have the particular area of the screen in which it is legal to draw. XUnless there is only one window in your application, you will have to test the Xhandle in the redraw request to figure out what to put in the rectangle.
X.PP
XDepending on the app, you may be drawing an AES object tree, or executing VDI Xcalls, or some combination of the two. In the AES case, the computed Xrectangle is used to specify the bounds of the objc_draw. For VDI Xwork, the rectangle is used to set the clipping area before executing Xthe VDI calls.
X.SH A SMALL CONFESSION
XAt the beginning of this discussion, I deliberately omitted one class of Xredraws: those initiated by the application itself.
XIn some cases a part of the screen must be redrawn immediately to give feedback Xto the user following a keystroke, button, or mouse action.   In these cases, Xthe application could call do_redraw directly, without waiting for a message.
X.PP
XThe only time you can bypass do_redraw, and draw without walking the rectangle Xlist, is when you can be sure that the target window is on top, and that the Xfigure being drawn is entirely contained within it.
X.PP
XIn many cases, however, an application initiated redraw happens because of a Xcomputed change, for instance, a spreadsheet update, and its timing is not Xcrucial. In this instance, you may wish to have the app send ITSELF a redraw Xrequest.
X.PP
XThe main advantage of this approach is that the AES is smart enough to see if Xthere is already a redraw request for the same window in the queue, and, if so, Xto merge the requests by doing a union of their rectangles. In this fashion, Xthe "blinky" appearance of multiple redraws is avoided, without the need to Xinclude logic for merging redraws within the program.
XA utility routine for sending the "self-redraw" is included in the Xdown-load for this article.
X.SH WINDOW CONTROL REQUESTS
XAn application is notified by the AES, via the message system, when the user Xmanipulates one of the window control points. Remember that you must have Xspecified each control point when the window was created, or will not receive Xthe associated control message.
X.PP

XThe most important thing to understand about window control is that the change
Xwhich the user requested does not take place until the application forwards it
Xto the AES. While this makes for a little extra work, it gives the program a
Xchance to intervene and validate or modify the request to suit.
X.PP
XA second thing to keep in mind is that not all window updates cause a redraw
Xrequest to be generated for the window, because the AES attempts to save time
Xwith raster moves on the screen.
XNow let's look at each window control request in detail. The message
Xcode for a window move is WM_MOVED. If you are willing to accept any
Xsuch request, just do:
X.FB wind_set()
Xwind_set(wh, WF_CXYWH, msg[4], msg[5], msg[6], msg[7]);
X.FE
X.sp 1
X.ce 1
X(Remember that wh, the window handle, is always in msg[3]).
X.sp 1
XThe AES will not request a redraw of the window following this call, unless the
Xwindow is being moved from a location which is partially "off-screen". Instead,
Xit will do a "blit" (raster copy) of the window and its contents to the new
Xlocation without intervention by the app.
X.PP
XThere are two constraints which you may often wish to apply to the user's move
Xrequest. The first is to force the new location to lie entirely within the
Xdesktop, rather than partially off-screen. You can do this with the
Xrc_constrain utility by executing:
X.FB rc_constrain()
Xrc_constrain(&full, &msg[4]);
X.FE
Xbefore making the wind_set call. (Full is assumed to contain the desktop
Xdimensions.)
X.PP
XThe second common constraint is to "snap" the x-dimension location of the new
Xlocation to a word boundary. This operation will speed up GEM's "blit" because
Xno shifting or masking will need to be done when moving the window. To perform
Xthis operation, use align() before the wind_set call:
X.FB align()
Xmsg[4] = align(msg[4], 16);
X.FE
XThe message code for a window size request is WM_SIZED. Again, if you are
Xwilling to accept any request, you can just "turn it around" with the same
Xwind_set call as given for WM_MOVED.
X.PP
XActually, GEM enforces a couple of constraints on sizing. First, the
Xwindow may not be sized off screen. Second, there is a minimum window
Xsize which is dependent on the window components specified when it was
Xcreated. This prevents features like scroll arrows from being
Xsqueezed into oblivion. The most common application constraint on
Xsizing is to snap the size to horizontal words (as above) and/or
Xvertical character lines. In the latter case, the vertical dimension
Xof the output font is used with align().
X.PP

XAlso, be aware that the size message which you receive specifies the
XEXTERNAL dimensions of the window. To assure an "even" size for the
XINTERNAL dimensions, you must make a wind_calc call to compute them,
Xuse align() on the computed values, back out the corresponding
Xexternal dimensions with the reverse wind_calc, and then make the
Xwind_set call with this set of values.
X.PP
XA window resize will only cause a redraw request for the window if the size is
Xbeing increased in at least one dimension. This is satisfactory for most
Xapplications, but if you must "reshuffle" the window after a size-down, you
Xshould send yourself a redraw (as described above) after you make the wind_set
Xcall. This will guarantee that the display is updated correctly. Also note
Xthat the sizing or movement of one window may cause redraw requests to be
Xgenerated for other windows which are uncovered by the change.
X.PP
XThe window full request, with code WM_FULLED, is actually a toggle. If the
Xwindow is already at its full size (as specified in the wind_create), then this
Xis a request to shrink to its previous size. If the window is currently small,
Xthen the request is to grow to full size.
X.PP
XSince the AES records the current, previous, and maximum window size,
Xyou can use wind_get calls to determine which situation pertains. The
Xhndl_full utility in the down-load (modified from Doodle), shows how
Xto do this.
X.PP
XThe "zoom box" effects when changing size are optional, and can be removed to
Xspeed things up. Again, if the window's size is decreasing, no redraw is
Xgenerated, so you must send yourself one if necessary. You should not have to
Xperform any constraint or "snap" operations here, since (presumably) the full
Xand previous sizes have had these checks applied to them already.
X.PP
XThe WM_CLOSED message is received when the close box is clicked. What
Xaction you perform depends on the application. If you want to remove
Xthe window, use wind_close as described in the last column. In many
Xapplications, however, the close message may indicate that a file is
Xto be saved, or a directory or editing level is to be closed. In
Xthese cases, the message is used to trigger this action before or
Xinstead of the wind_close. (Folders on the Desktop are an example of
Xthis situation.)
X.PP
XThe WM_TOPPED message indicates that the AES wants to bring the
Xindicated window to the "top" and make it active. This happens if the
Xuser clicks within a window which is not on top, or if the currently
Xtopped window is closed by its application or desk accessory.
XNormally, the application should respond to this message with:
X.FB wind_set()
Xwind_set(wh, WF_TOP, 0, 0);
X.FE
Xand allow the process to complete.
X.PP
XIn a few instances, a window may be used in an output only mode, such as a
Xstatus display, with at least one other window present for input. In
Xthis case, a WM_TOPPED message for the status window may be ignored.

XIn all other cases, you must handle the WM_TOPPED message even if your
Xapplication has only one window: Invocation of a desk accessory could
Xalways place another window on top. If you fail to do so, subsequent
Xredraws for your window may not be processed correctly.
X.SH WINDOW SLIDER MESSAGES
XIf you specify all of the slider bar parts for your window, you may receive up
Xto five different message types for each of the two sets of sliders. To
Xsimplify things a little, I will discuss everything in terms of the vertical
X(right hand side) sliders. If you are also using the horizontal sliders, the
Xsame techniques will work, just use the alternate mnemonics.
X.PP
XThe WM_VSLID message indicates that the user has dragged the slider bar within
Xits box, indicating a new relative position within the document.
XAlong with the window handle, this message includes the relative
Xposition between 1 and 1000 in msg[4].
X.PP
XRecall from last column's discussion that this interval corresponds to the
X"freedom of movement" of the slider. If you want to accept the user's request,
Xjust make the call:
X.FB wind_set
Xwind_set(wh, WF_VSLIDE, msg[4], 0, 0, 0);
X.FE
X.sp 1
X.ce 1
X(Corresponding horizontal mnemonics are WM_HSLID and WF_HSLIDE).
X.sp 1
XNote that this wind_set call will not cause a redraw message to be sent. You
Xmust update the display to reflect the new scrolled position, either by
Xexecuting a redraw directly, or by sending yourself a message.
X.PP
XIf the document within the window has some structure, you may not wish
Xto accept all slider positions. Instead you may want to force the
Xscroll position to the nearest text line (for instance). Using terms
Xdefined in the last column, you may convert the slider position to
X"document units" with:
X.sp 1
X.ce 1
Xtop_wind = msg[4] * (total_doc - seen_doc) / 1000 + top_doc
X.sp 1
X.ce 1
X(This will probably require 32-bit arithmetic).
X.sp 1
XAfter rounding off or otherwise modifying the request, convert it back
Xto slider units and make the WF_VSLIDE request.
X.PP
XThe other four slider requests all share one message code: WM_ARROWED.
XThey are distinguished by sub-codes stored in msg[4]: WA_UPPAGE,
XWA_DNPAGE, WA_UPLINE, and WA_DNLINE. These are produced by clicking
Xabove and below the slider, and on the up and down arrows,
Xrespectively. (I have no idea why sub-codes were used in this one
Xinstance.) The corresponding horizontal slider codes are:
XWA_LFPAGE, WA_RTPAGE, WA_LFLINE, and WA_RTLINE.
X.PP

XWhat interpretation you give to these requests will depend on the application.
XIn the most common instance, text documents, the customary method is to change
Xthe top of window position (top_wind) by one line for a WA_UPLINE or
XWA_DNLINE, and by seen_doc (the number of lines in the window) for a
XWA_UPPAGE or WA_DNPAGE.
X.PP
XAfter making the change, compute a new slider position, and make the wind_set
Xcall as given above. If the document's length is not an even multiple of
X"lines" or "pages" you will have to be careful that incrementing or
Xdecrementing top_wind does not exceed its range of freedom: top_doc to (top_doc
X+ total_doc - seen_doc).
X.PP
XIf you have such an odd size document, you will also have to make a decision on
Xwhether to violate the line positioning rule so that the slider may be put at
Xits bottom-most position, or to follow the rule but make it impossible to get
Xthe slider to the extreme of its range.
X.SH A COMMON BUG
XIt is easy to forget that user clicks are not the only things that
Xaffect slider position. If the window size changes as a result of a
XWM_SIZED or WM_FULLED message, the app must also update its sliders
X(if they are present). This is a good reason to keep the top of
Xwindow information in "document units".
X.PP
XYou can just redo the position calculation with the new "seen_doc" value, and
Xcall wind_set. Also remember that changing the size of the
Xunderlying document (adding or deleting a bottom line, for instance)
Xmust also cause the sliders to be adjusted.
X.SH DEPT. OF DIRTY TRICKS
XThere are two remaining window calls which are useful to advanced programmers.
XThey require techniques which I have not yet discussed, so you may need to file
Xthem for future reference.
X.PP
XThe AES maintains a quarter-screen sized buffer which is used to save the area
Xunder alerts and menu drop-downs. It is occasionally useful for the
Xapplication to gain access to this buffer for its own use in saving
Xscreen areas with raster copies. To do so, use:
X.FB wind_get()
Xwind_get(0, WF_SCREEN, &loaddr, &hiaddr, &lolen, &hilen);
X.FE
XHiaddr and loaddr are the top and bottom 16-bits (respectively) of the 32-bit
Xaddress of the buffer. Hilen and lolen are the two halves of its length.
X.PP
XDue to a preculiarity of the binding you have to reassemble these
Xpieces before using them. (The actual value of WF_SCREEN is 17; this
Xdoes not appear in some versions of the GEMDEFS.H file.)
X.PP
XIf you use this buffer, you MUST prevent menus from dropping down by using
Xeither the BEG_UPDATE or BEG_MCTRL wind_update calls. Failure to do so will
Xresult in your data being destroyed. Remember to use the matching wind_update:
XEND_UPDATE or END_MCTRL, when you are done.
X.PP
XThe other useful call enables you to replace the system's desktop definition
Xwith a resource of your choosing. The call:

```
X.FB wind_set()
Xwind_set(0, WF_NEWDESK, tree, 0, 0);
X.FE
Xwhere tree is the 32-bit address of the object tree, will cause the AES to draw
Xyour definition instead of the usual gray or green background. Not
Xonly that, it will continue to redraw this tree with no intervention
Xon your part.
X.PP
XObviously, the new definition must be carefully built to fit the desktop area
Xexactly or garbage will be left around the edges.  For the truly sophisticated,
Xa user-defined object could be used in this tree, with the result that your
Xapplication's code would be entered from the AES whenever the desktop was
Xredrawn.  This would allow you to put VDI pictures or complex images onto the
Xdesktop background.
X.SH A SIN OF OMISSION
XIn the last column, I neglected to mention that strings whose addresses are
Xpassed in the WF_NAME and WF_INFO  wind_set calls must be allocated in a static
Xdata area.  Since the AES remembers the addresses (not the characters), a
Xdisaster may result if the storage has been reused when the window manager next
Xattempts to draw the window title area.
X.SH COMING SOON
XThis concludes our tour of GEM's basic window management techniques. There have
Xbeen some unavoidable glimpses of paths not yet taken (forward references), but
Xwe will return in time.
X.PP
XOn our next excursion, we will take a look at techniques for handling simple
Xdialog boxes, and start exploring the mysteries of resources and object trees.

X.PART III THE DIALOG HANDLER
X.SH A MEANINGFUL DIALOG
XThis issue of ST PRO GEM begins an exploration of ST GEM's dialog handler. I
Xwill discuss basic system calls for presenting the dialog, and then continue
Xwith techniques for initializing and reading on/off button and "radio" button
Xobjects. We will also take some short side-trips into the operation
Xof the GEM Resource Construction Set to assist you in building these dialogs.
X.PP
XThere are a number of short C routines which accompany this column. These are
Xstored as file GEMCL3.XMO in DL 5 on SIG*ATARI. Before reading this column, you
Xshould visit SIG*ATARI (go pcs-132) and download this file.
X.PP
X.SH DEFINING TERMS
XA dialog box is an "interactive form" in which the user may enter text and
Xindicate selections by pointing with the mouse. Dialogs in GEM are
X"modal", that is, when a dialog is activated other screen functions
Xsuch as menus and window controls are suspended until the dialog is completed.
X.PP
XIn most cases, the visual structure of a GEM dialog is specified within your
Xapplication's resource file. The GEM Resource Construction Set (RCS)
Xis used to build a picture of the dialog.
X.PP
XWhen the RCS writes out a resource, it converts that picture into a tree of
XGEM drawing objects and stores this data structure within the resource. Before
Xyour application can display the dialog, it must load this resource file and
Xfind the address of the tree which defines the dialog.
X.PP
XTo load a resource, the AES checks its size and allocates memory for the
Xload. It then reads in the resource, adjusting internal pointers to
Xreflect the load address. Finally, the object sizes stored in the
Xresource are converted from characters to pixels using the system font size.
X.PP
XA note for those with Macintosh experience: Although Mac and GEM resources
Xshare a name, there are fundamental differences which can be misleading. A Mac
Xresource is a fork within a file; a GEM resource is a TOS file by itself. Mac
Xresources may be paged in and out of memory; GEM resources are monolithic. GEM
Xresources are internally tree structured; Mac resources are not. Finally, Mac

Xresources include font information, while ST GEM does this with font loading at
Xthe VDI level.
X.PP
XThe resource load is done with the GEM AES call:
X.FB rsrc_load()
Xok = rsrc_load(ADDR("MYAPP.RSC"));
X.FE
X"MYAPP" should be replaced with the name of your program. Resources
Xconventionally have the same primary name as their application, with the RSC
Xextent name instead of PRG. The ok flag returned by rsrc_load will be FALSE is
Xanything went wrong during the load.
X.PP
XThe most common causes of failure are the resource not being in the
Xapplication's subdirectory, or lack of sufficient memory for GEM to allocate
Xspace for the resource. If this happens, you must terminate the program
Ximmediately.
X.PP
XOnce you have loaded the resource, you find the address of a dialog's object
Xtree with:
X.FB rsrc_gaddr()
Xrsrc_gaddr(R_TREE, MYDIALOG, &tree);
X.FE
XTree is a 32-bit variable which will receive the address of the root
Xnode of the tree.
X.PP
XThe mnemonic MYDIALOG should be replaced with the name you gave your dialog
Xwhen defining it in the RCS. At the same time that it writes the resource, RCS
Xgenerates a corresponding .H file containing tree and object names.
XIn order to use these mnemonics within your program, you must include
Xthe name file in your compile: #include "MYAPP.H"
X.SH BUG ALERT!
XWhen using the DRI/Alcyon C compiler, .H files must be in the compiler's home
Xdirectory or they will not be found. This is especially annoying using a two
Xfloppy drive ST development system. The only way around this is to explicitly
Xreference an alternate disk in the #include, for instance: "B:MYAPP.H".
X[Ed. Note: Use the -i flag with the C pre-processor to name the include
Xdirectories].
X.PP
XNow that the address of the dialog tree has been found, you are ready to
Xdisplay it. The standard (and minimal) sequence for doing so is given in
Xroutine hndl_dial() in the download. We will now walk through each
Xstep in this procedure.
X.PP
XThe form_center call establishes the location of the dialog on the screen.
XDialog trees generated by the RCS have an undefined origin (upper-left corner).
X.PP
XForm_center computes the upper-left location necessary to center the dialog
Xon the screen, and inserts it into the OB_X and OB_Y fields of the ROOT object
Xof the tree. It also computes the screen rectangle which the dialog
Xwill occupy on screen and writes its pixel coordinates into variables
Xxdial, ydial, wdial, and hdial.
X.PP
XThere is one peculiarity of form_center which occasionally causes trouble.

XNormally the rectangle returned in xdial, etc., is exactly the same size as the
Xbasic dialog box.
X.PP
XHowever, when the OUTLINED enhancement has been specified for the box,
Xform_center adds a three pixel margin to the rectangle returned. This
Xcauses the screen area under the outline to be correctly redrawn later
X(see below). Note that OUTLINED is part of the standard dialog box in
Xthe RCS. Other enhancements, such as SHADOWED or "outside" borders
Xare NOT handled in this fashion, and you must compensate for them in
Xyour code.
X.PP
XThe next part of the sequence is a form_dial call with a zero parameter.
XThis reserves the screen for the dialog action about to occur. Note that the C
Xbinding given for form_dial in the DRI documents is in error: there are nine
Xparameters, not five. The first set of xywh arguments is actually used with
Xform_dial calls 1 and 2 only, but place holders must be supplied in all cases.
X.PP
XThe succeeding form_dial call (parameter one) animates a "zoom box" on the
Xscreen which moves and grows from the first screen rectangle given to
Xthe second rectangle, where the dialog will be displayed.
X.PP
XThe use of this call is entirely optional. In choosing whether to use it or
Xnot, you should consider whether the origin of the "zoom" is relevant to the
Xoperation. For instance, a zoom from the menu bar is relatively meaningless,
Xwhile a zoom from an object about to be edited in the dialog provides visual
Xfeedback to the user, showing whether the correct object was chosen.
X.PP
XIf the origin is not relevant, then the zoom is just a time-waster. If you
Xdecide to include these effects, consider a "preferences" option in your app
Xwhich will allow the experienced and jaded user to turn them off in the
Xinterests of speed.
X.PP
XThe objc_draw call actually displays the dialog on the screen. Note that the
Xaddress of the tree, the beginning drawing object, and the drawing depth are
Xpassed as arguments, as well as the rectangle allotted for the dialog.
X.PP
XIn general, dialogs (and parts of dialogs) are ALWAYS drawn beginning at the
XROOT (object zero). When you want to draw only a portion of the
Xdialog, adjust the clipping rectangle, but not the object number.
XThis ensures that the background of the dialog is always drawn correctly.
X.PP
XThe objc_xywh() utility in the download can be used to find the clipping
Xrectangle for any object within a dialog, though you may have to allow an extra
Xmargin is you have used shadows, outlines, or outside borders with the object.
X.PP
XCalling form_do transfers control to the AES, which animates the dialog for
Xuser interaction. The address of the dialog tree is passed as a
Xparameter. The second paramter is the number of the editable object
Xat which the text cursor will first be positioned. If you have no text
Xfields, pass a zero. Note that again the DRI documents are in error:
Xpassing a -1 default may crash the system. Also be careful that the
Xdefault which you specify is actually a text field; no error checking
Xis performed.

X.PP
XThe form_do call returns the number of the object on which the clicked to
Xterminate the dialog. Usually this is a button type object with the EXIT and
XSELECTABLE attributes set. Setting the DEFAULT attribute as well will cause an
Xexit on that object is a carriage return is struck while in the dialog.
X.PP
XIf the top bit of the return is set, it indicates that the exit object had
Xthe TOUCHEXIT attribute and was selected with a double-click. Since very few
Xdialogs use this combination, the sample code simply masks off the top bit.
X.PP
XThe next form_dial call reverses the "zoom box", moving it from the dialog's
Xlocation back to the given x,y,w,h. The same cautions apply here as above.
X.PP
XThe final form_dial call tells GEM that the dialog is complete, and that the
Xscreen area occupied by the dialog is now considered "dirty" and needs to be
Xredrawn. Using the methods described in our last column, GEM then
Xsends redraws to all windows which were overlaid, and does any
Xnecessary redrawing of the menu or desktop itself.
X.PP
XThere is one notable "feature" of form_dial(3): It always redraws an area
Xwhich is two pixels wider and higher than your request! This was probably
Xincluded to make sure that drop-shadows were cleaned up, and is usually
Xinnocuous.
X.SH A HANDY TRICK
XUse of the form_dial(3) call is not limited to dialogs. You can use
Xit to force the system to redraw any part of the screen. The
Xadvantage of this method is that the redraw area need not lie entirely
Xwithin a window, as was necessary with the send_redraw method detailed
Xin the last column. A disadvantage is that this method is somewhat
Xslower, since the AES has to decide who gets the redraws.
X.SH CLEAN UP
XAs a last step, you need to clear the SELECTED flag in the object which was
Xclicked. If you do not do this, the object will be drawn inverted the next
Xtime you call the dialog. You could clear the flag with the GEM objc_change
Xcall, but it is inefficient since you do not need to redraw the object.
X.PP
XInstead, use the desel_obj() code in the download, which modifies the
Xobject's OB_STATE field directly. Assuming that ret_obj contains the exit
Xobject returned by hndl_dial, the call:
X.FB desel_obj()
Xdesel_obj(tree, ret_obj);
X.FE
Xwill do the trick.
X.SH RECAP
XThe basic dialog handling method I have described contains three steps:
Xinitialization (rsrc_gaddr), dialog presentation (hndl_dial), and cleanup
X(desel_obj).
X.PP
XAs we build more advanced dialogs, these same basic steps will be performed,
Xbut they will grow more complex. The initialization will include setting up
Xproper object text and states, and the cleanup phase will also interrogate the
Xfinal states of objects to find out what the user did.
X.SH BUTTON, BUTTON

XThe simple dialogs described above contain only exit buttons as active objects.
XAs such, they are little more than glorified alert boxes.
X.PP
XWe will now increase the complexity a little by considering non-exit buttons.
XThese are constructed by setting the SELECTABLE attribute on a button object.
XAt run-time, such an object will toggle its state between selected
X(highlighted) and non-selected whenever the user clicks on it. (You
Xcan set the SELECTABLE attribute of other types of objects and use
Xthem instead of actual buttons, but be sure that the user will be
Xable to figure out what you intend!)
X.PP
XHaving non-exit buttons forces us to consider the problem of initializing
Xthem before the dialog, and interrogating and resetting them afterward.
X.PP
XSince a button is a toggle, it is usually associated with a flag variable in
Xthe program. As part of the initialization, you should test the flag variable,
Xand if true call:
X.FB sel_obj()
Xsel_obj(tree, BTNOBJ);
X.FE
Xwhich will cause the button to appear highlighted when the dialog is first
Xdrawn. Sel_obj() is in the download. BTNOBJ is replaced with the name you
Xgave your button when you defined it in the RCS. Since the button starts out
Xdeselected, you don't have to do anything if your flag variable is false.
X.PP
XAfter the dialog has completed, you need to check the object's state. The
Xselectp() utility does so by masking the OB_STATE field. You can simply assign
Xthe result of this test to your flag variable, but be sure that the dialog was
Xexited with an OK button, not with a CANCEL! Again, remember to clean up the
Xbutton with desel_obj(). (It's often easiest to deselect all buttons
Xjust before you leave the dialog routine, regardless of the final
Xdialog state.)
X.SH WHO'S GOT THE BUTTON?
XAnother common use of buttons in a dialog is to select one of a set
Xof possible options. In GEM, such objects are called radio buttons.
XThis term recalls automobile radio tuners where pushing in one button
Xpops out any others. In like fashion, selecting any one of a set of
Xradio buttons automatically deselects all of the others.
X.PP
XTo use the radio button feature, you must do some careful work with the
XResource Construction Set.
X.PP
XFirst, each member of a set of radio buttons must be children of the same
Xparent object within the object tree. To create this structure, put a hollow
Xbox type object in the dialog, make it big enough to hold all of the buttons,
Xand then put the buttons into the box one at a time.
X.PP
XBy nesting the buttons within the box object, you force them to be its
Xchildren. Each of the buttons must have both the SELECTABLE and RADIO BUTTON
Xattributes set. When you are done, you may make the containing box
Xinvisible by setting its border to zero, but do not FLATTEN it!
X.PP
XSince each radio button represents a different option, you must usually

Xassign a name to each object. When initializing the dialog, you must check
Xwhich option is currently set, and turn on the corresponding button only. A
Xchain of if-then-else structures assures that only one button will be selected.
X.PP
XAt the conclusion of the dialog, you must check each button with selectp()
Xand make the appropriate adjustments to internal variables. Again, an
Xif-then-else chain is appropriate since only one button may be
Xselected. Either deselect the chosen button within this chain or do
Xthem all at the end.
X.PP
XThere is one common use of radio buttons in which you may short-cut this
Xprocedure. If the buttons each represent one possible value of a numeric
Xvariable, for instance, a set of selector buttons representing colors
Xfrom zero to seven, then you can compute the initial object directly.
X.PP
XIn order for this technique to work, you must use a special capability of the
XRCS. Insert the object corresponding to a zero value at the top (or left) of
Xyour array of buttons, then put the "one" button below (or right) of it, and so
Xon.
X.PP
XWhen the buttons are complete, the SORT operation is used to guarantee that
Xthe top/left object is in fact the first child of the parent box with
Xthe others following in order. Due to the details of object tree
Xstructure (to be discussed in the next column), this will guarantee
Xthat these objects are contiguous in the resource.
X.PP
XIf you assign a name (say BUTTON1) to the first button, then you can
Xinitialize the correct button with the call:
X.FB sel_obj()
Xsel_obj(tree, BUTTON1 + field);
X.FE
Xwhere field is the variable of interest.
X.PP
XWhen the dialog is complete, you can scan the radio buttons to compute the
Xnew value for the underlying variable. The encode() procedure in the download
Xwill do this. As always, remember to deselect the buttons at the end.
X.PP
XYou can use offsets or multipliers if your variable's values don't start with
Xzero or increment by one. If the values are irregular you may be able to use a
Xlookup table, at the cost of additional code.
X.SH COMING UP NEXT
XIn the next column, I will discuss the internal structure of object
Xtrees. Then we'll use that knowledge to build a piece of code which
Xwill "walk" an entire tree and apply a function to each object. We'll
Xapply this code to do all of the button deselects with a single call!
XI'll also look at handling editable text fields and discuss some ways
Xto alter a dialog's appearance at run-time.
X.SH DISPELL GREMLINS
XAn editing error caused an omission in the first installment of ST PRO
XGEM. The window components RTARROW and DNARROW should have been
Xlisted along with HSLIDE as the horizontal equivalents of the vertical
Xslider components which were discussed.

X.PART IV Resource Structure
X.PP
XWelcome to the fourth installment of ST PRO GEM.  We are about to delve into
Xthe mysteries of GEM resource structure, and then use this knowledge to create
Xsome useful utilities for handling dialogs.  As with the past columns, there is
Xonce again a download file.  You will find it under the name GEMCL4.C in the
XATARI 16-bit Forum (GO PCS-58).
X.PP
XThe first and largest part of the download contains a C image of a sample
Xresource file.  To create this listing, I used the GEM Resource  Construction
XSet to create a dummy resource with three dialogs including examples of all
Xobject types, then enabled the C output option and saved  the resource.  If you
Xhave access to a copy of RCS, I suggest that you  create your own listing in
Xorder to get a feel for the results.  Then, using  either listing as a roadmap
Xto the resource, you can follow along as  we enter...
X.SH A MAZE OF TWISTY LITTLE PASSAGES.
XWhile a GEM resource is loaded as a block of binary information, it
Xis actually composed of a number of different data structures.  These
Xstructures are linked together in a rather tangled hierarchy.  Our
Xfirst job is to map this linkage system.
X.PP
XThe topmost structure in a resource file is the resource header. This is an
Xarray of words containing the size and offset within the resource of the other
Xstructures which follow.  This information is used by  GEM during the resource
```

Xload process, and you should never need to access it. (The resource header does
Xnot appear in the C output file; it is generated by the RSCREATE utility if the
XC file is used to recreate the resource.)
X.PP
XThe next structure of interest is the tree index. This is an array of long
Xpointers, each of which addresses the beginning of an object tree. Again, you
Xwouldn't normally access this structure directly. The GEM rsrc_gaddr call uses
Xit when finding trees' addresses. This structure is called "rs_trindex" in the
XC output.
X.PP
XIf you look at the contents of rs_trindex you will notice that the values are
Xintegers, instead of the pointers I described. What has happened is that RCS
Xhas converted the pointers to indices into the object array. (If you actually
Xused the C file to recreate the resource file, then the pointers would be
Xregenerated by RSCREATE.)
X.PP
XNow you can follow the link from rs_trindex to the objects stored in
Xrs_object. Take (for instance) the second entry in rs_trindex and count down
Xthat many lines in rs_object. The following line (object) should start with a
X-1. This indicates that it is the root object of a tree. The following objects
Xdown to the next root belong to that tree. We'll pass over the details of
Xinter-object linkage for now, leaving it for a later column.
X.PP
XThere are a number of different fields in an object, but right now we'll
Xconcentrate on two of them: OB_TYPE and OB_SPEC. The OB_TYPE is the field which
Xcontains mnemonics like G_STRING and G_BOX indicating the type of the object.
XThe OB_SPEC is the only field in each object which is a LONG - you can tell it
Xby the L after the number.
X.PP
XWhat's in OB_SPEC depends on the object type, so we need to talk about what
Xkinds of objects are available, what you might use them for, and finally how
Xthey use the OB_SPEC field.
X.PP
XThe box type objects are G_BOX, G_IBOX, and G_BOXCHAR. A G_BOX is an opaque
Xrectangle, with an optional border. It's used to create a solid patch of color
Xor pattern on which to place other objects. For instance, the background of a
Xdialog is a G_BOX.
X.PP
XA G_IBOX is a hollow box which has only a border. (If the border has no
Xthickness, then the box is "invisible", hence the name.) The favorite use for
XIBOXes is to hold radio buttons. There is also one neat trick you can play with
Xan IBOX. If you have more than one object (say an image and a string) which you
Xwould like to have selected all at once, you can insert them in a dialog, then
Xcover them with an IBOX. Since the box is transparent, they will show through.
XIf you now make the box selectable, clicking on it will highlight the whole area
Xat once!
X.PP
XThe G_BOXCHAR is just like a G_BOX, except that a single character is drawn
Xin its center. They are mostly used as "control points": the FULLER, CLOSER,
XSIZER, and arrows in GEM windows are BOXCHARs, as are the components of the
Xcolor selection gadgets in the RCS.
X.PP
XThe OB_SPEC for box type objects is a packed bit array. Its various fields

Xcontain the background color and pattern, the border thickness and color, and
Xthe optional character and its color.
X.PP
XThe string type objects are G_STRING, G_BUTTON, and G_TITLE. G_STRINGs (in
Xaddition to being a bad pun) are for setting up static explanatory text within
Xdialogs. The characters are always written in the "system font": full size,
Xblack, with no special effects.
X.PP
XWe have already discussed many of the uses of G_BUTTONs. They add a border
Xaround the text. The thickness of a G_BUTTON's border is determined by what
Xflags are set for the object. All buttons start out with a border thickness of
Xone pixel. One pixel is added if the EXIT attribute is set, and one more is
Xadded if the DEFAULT attribute is set.
X.PP
XThe G_TITLE type is a specially formatted text string used only in the title
Xbar of menus. This type is needed to make sure that the menus redraw correctly.
XThe Resource Construction Set automatically handles inserting G_TITLEs, so you
Xwill seldom use them directly.
X.PP
XIn a resource, the OB_SPEC for all string objects is a long pointer to a null
Xterminated ASCII string. The string data in the C file is shown in the BYTE
Xarray rs_strings. Again you will notice that the OB_SPECs in the C file have
Xbeen converted to indices into rs_string. To find the string which matches the
Xobject, take the value of OB_SPEC and count down that many lines in rs_strings.
XThe next line is the correct string.
X.PP
XThe formatted text object types are G_TEXT, G_BOXTEXT, G_FTEXT, and
XG_FBOXTEXT. G_TEXTs are a lot like strings, except that you can specify a
Xcolor, different sizes, and a positioning rule for the text.   Since they
Xrequire more memory than G_STRINGs, G_TEXTs should be used sparingly to draw
Xattention to important information within a dialog.   G_TEXTs are also useful
Xfor automatic centering of dialog text which is changed at run-time. I will
Xdescribe this technique in detail later on.
X.PP
XThe G_BOXTEXT type adds a solid background and border to the G_TEXT type.
XThese objects are occasionally used in place of G_BUTTONs when their color will
Xdraw attention to an important object.
X.PP
XThe G_FTEXT object is an editable text field. You are able to specify a
Xconstant "template" of characters, a validation field for those characters which
Xare to be typed in, and an initial value for the input characters. You may also
Xselect color, size, and positioning rule for G_FTEXTs. We'll discuss text
Xediting at length below.
X.PP
XThe G_FBOXTEXT object, as you might suspect, is the same as G_FTEXT with the
Xaddition of background and border. This type is seldom used: the extra
Xappearance details distract attention from the text being edited.
X.PP
XThe OB_SPEC for a formatted text object is a pointer to yet another type of
Xstructure: a TEDINFO. In the C file, you will find these in rs_tedinfo. Take
Xthe OB_SPEC value from each text type object and count down that many entries in
Xrs_tedinfo, finding the matching TEDINFO on the next line. Each contains
Xpointers to ASCII strings for the template, validation, and initialization. You

Xcan find these strings in rs_strings, just as above.
X.PP
XThere are also fields for the optional background and border details, and for Xthe length of the template and text. As we will see when discussing editing, Xthe most important TEDINFO fields are the TE_PTEXT pointer to initialized text Xand the TE_TXTLEN field which gives its length.
X.PP
XThe G_IMAGE object type is the only one of its kind. A G_IMAGE is a Xmonochrome bit image. For examples, see the images within the various GEM alert Xboxes. Note that monochrome does not necessarily mean black. The image may be Xany color, but all parts of it are the SAME color. G_IMAGEs are used as visual Xcues in dialogs. They are seldom used as selectable items because their entire Xrectangle is inverted when they are clicked. This effect is seldom visually Xpleasing, particularly if the image is colored.
X.PP
XG_IMAGE objects have an OB_SPEC which is a pointer to a further structure Xtype: the BITBLK. By now, you should guess that you will find it in the C file Xin the array rs_bitblk. The BITBLK contains fields describing the height and Xwidth of the image in pixels, its color,nd it also contains a long pointer to Xthe actual bits which make up the image. In the C file, the images are encoded Xas hexadecimal words and stored in arrays named IMAG0, IMAG1, and so on.
X.PP
XThe last type of object is the G_ICON. Like the G_IMAGE, the G_ICON is a bit Ximage, but it adds a mask array which selects what portions of the image will be Xdrawn, as well as an explanatory text field. A G_ICON may also specify Xdifferent colors for its "foreground" pixels (the ones that are normally black), Xand its "background" pixels (which are normally white).
X.PP
XThe pictures which you see in Desktop windows are G_ICONs, and so are the Xdisks and trashcan on the desktop surface. With the latter you will notice the Xeffects of the mask. The desktop shows through right up to the edge of the XG_ICON, and only the icon itself (not a rectangle) is inverted when a disk is Xselected.
X.PP
XThe OB_SPEC of an icon points to another structure called an ICONBLK. It is Xshown in the C file as rs_iconblk. The ICONBLK contains long pointers to its Xforeground bit array, to the mask bit array, and to the ASCII string of Xexplanatory text. It also has the foreground and background colors as well as Xthe location of the text area from the upper left of the icon. The most common Xuse of G_ICONs and ICONBLKs is not in dialogs, instead they are used frequently Xin trees which are build at run-time, such as Desktop windows. In a future Xarticle, we will return to a discussion of building such "on-the-fly" trees with XG_ICONs.
X.PP
XNow, let's recap the hierarchy of resource structures: The highest level Xstructures are the resource header, and then the tree index. The tree index Xpoints to the beginning of each object tree. The objects making up the tree are Xof several types, and depending on that type, they may contain pointers to ASCII Xstrings, or to TEDINFO, ICONBLK, or BITBLK structures. TEDINFOs contain further Xpointers to strings; BITBLKs have pointers to bit images; and ICONBLKs have Xboth.
X.SH PUTTING IT TO WORK
XThe most common situations requiring you to understand

Xresource structures involve the use of text and editable text objects in
Xdialogs. We'll look at two such techniques.
X.PP
XOften an application requires two or more dialogs which are very similar
Xexcept for one or two title lines. In this circumstance, you can save a good
Xdeal of resource space by building only one dialog, and changing the title at
Xrun time.
X.PP
XIt is easy to go wrong with this practice, however, because the obvious
Xtactic of using a G_STRING and writing over its text at run time can go wrong.
XThe first problem is that you must know in advance the longest title to be used,
Xand put a string that long into the resource. If you don't you will damage other
Xobjects in the resource as you copy in characters. The other problem is that a
XG_STRING is always drawn at the same place in a dialog. If the length of the
Xtitle changes from time to time, the dialog will have an unbalanced and sloppy
Xappearance.
X.PP
XA better way to do this is to exploit the G_TEXT object type, and the TEDINFO
Xstructure. The set_text() routine in the download shows how. The parameters
Xprovided are the tree address, the object number, and the 32-bit address of the
Xstring to be substituted. For this to work, the object referenced should be
Xdefined as a G_TEXT type object.   Additionally, the Centered text type should
Xbe chosen, and the object should have been "stretched" so that it fills the
Xdialog box from side to side.
X.PP
XIn the code, the first action is to get the OB_SPEC from the object which was
Xreferenced. Since we know that the object is a G_TEXT, the OB_SPEC must point
Xto a TEDINFO. We need to change two fields in the TEDINFO. The TE_PTEXT field
Xis the pointer to the actual string to be displayed; we replace it with the
Xaddress of our new string. The TE_TXTLEN field is loaded with the new string's
Xlength. Since the Centered attribute was specified for the object, changing the
XTE_TXTLEN will cause the string to be correctly positioned in the middle of the
Xdialog!
X.PP
XEditing text also requires working with the TEDINFO structure. One way of
Xdoing this is shown in the download. The object to be used (EDITOBJ) is assumed
Xto be a G_FTEXT or G_FBOXTEXT. Since we will replace the initialized text at
Xrun time, that field may be left empty when building the object in the RCS.
X.PP
XThe basic trick of this code is to point the TEDINFO's TE_PTEXT at a string
Xwhich is defined in your code's local stack. The advantages of this technique
Xare that you save resource space, save static data by putting the string in
Xreusable stack memory, and automatically create a scratch string which may be
Xdiscarded if the dialog is cancelled.
X.PP
XThe text string shown is arbitrarily 41 characters long. You should give
Xyours a length equal to the number of blanks in the object's template field plus
Xone. Note that the code is shown as a segment, rather than a subroutine. This
Xis required because the text string must be allocated within the context of
Xdialog handling routine itself, rather than a routine which it calls!
X.PP
XAfter the tree address is found, the code proceeds to find the TEDINFO and
Xmodify its TE_PTEXT as described above. However, the length which is inserted

Xinto TE_TXTLEN must be the maximum string length, including the null!
X.PP
XThe final line of code inserts a null into the first character of the
Xuninitialized string. This will produce an empty editing field when the dialog
Xis displayed. If there is an existing value for the object, you
Xshould instead use strcpy() to move it into text[]. Once the dialog is
Xcomplete, you should check its final status as described in the last
Xarticle. If an "OK" button was clicked, you will then use strcpy() to
Xmove the value in text[] back to its static location.
X.PP
XAlthough I prefer this method of handling editable text, another method
Xdeserves mention also. This procedure allocates a full length text string of
Xblanks when creating the editable object in the RCS. At run-time, the TE_PTEXT
Xlink is followed to find this string's location in the resource, and any
Xpre-existing value is copied in. After the dialog is run, the resulting value is
Xcopied back out if the dialog completed successfully.
X.PP
XNote that in both editing techniques a copy of the current string value is
Xkept within the application's data area. Threading the resource whenever you
Xneed to check a string's value is extremely wasteful.
X.PP
XOne final note on editable text objects: GEM's editor uses the commercial at
Xsign '@' as a "meta-character". If it is the first byte of the initialized
Xtext, then the field is displayed blank no matter what follows. This can be
Xuseful, but is sometimes confusing when a user in all innocence enters an @ and
Xhas his text disappear the next time the dialog is drawn!
X.SH LETTERS, WE GET LETTERS
XThe Feedback section on ANTIC ST ONLINE is now
Xfunctional and is producing a gratifying volume of response. A number of
Xrequests were made for topics such as ST hardware and ST BASIC which are beyond
Xthe intended scope of this column. These have been referred to ANTIC's
Xeditorial staff for action.
X.PP
XSo many good GEM questions were received that I will devote part of the next
Xcolumn to answering several of general interest. Also, your requests have
Xresulting in scheduling future columns on VDI text output and on the principles
X(or mythology) of designing GEM application interfaces. Finally, a tip of the
Xhat to the anonymous reader who suggested including the actual definitions of
Xall macro symbols, so that those without the appropriate H files can follow
Xalong. As a result of this suggestion, the definitions for this column and the
Xprevious three are included at the end of the download. Future articles will
Xcontinue this practice.
X.SH STRAW POLL!
XI'd like to make a practice of using the Feedback to get your
Xopinions on the column's format. As a first trial, I'd like to know your
Xfeelings about my use of "portability macros" in the sample code. These macros,
XLLGET for example, are used for compatibility between 68K GEM systems like the
XST, and Intel based systems like the IBM PC. This may be important to many
Xdevelopers. On the other hand, omitting them results in more natural looking C
Xcode. For instance, in the download you will find a second version of
Xset_text() as described above, but without the portability macros. So, I would
Xlike to know if you think we should (A) Keep the macros - portability is
Ximportant to serious developers, (B) Get rid of them - who cares about Intel

```
Xchips anyway, or (C) Who cares? I'll tally the votes in two weeks and announce
Xthe results here.
X.SH STAY TUNED!
XAs well as answers to feedback questions, the next column will
Xdiscuss how GEM objects are linked to form trees, and how to use AES calls and
Xyour own code to manipulate them for fun and profit.  In the following
Xinstallment, we'll look at the VDI raster operations (also known as "blit"
Xfunctions).

X.PART V Resource Tree Structures
X.PP
XThis is the fifth issue of ST PROFESSIONAL GEM, concluding our
```

Xtrek through GEM dialogs and resources with a look at the internal
Xstructure of object trees. Also, I'll answer a number of questions
Xof general interest which have been received via the ANTIC ONLINE
XFEEDBACK. As always, there is a download file associated with this
Xcolumn: GEMCL5.C, which you will find in DL3 of the new Atari 16-bit
XSIG (type GO PCS-58 or GO ATARI16).
X.PP
XEven if you have no immediate use for this issue's code, be sure
Xto take the download anyway; some of the routines will be used in
Xlater articles.
X.PP
XIn the last installment, we established that resources trees are
Xpointed to by the tree index, and that they are composed of objects
Xwhich contain pointers onward to other structures. However, we
Xpassed over the issue of linkage among the objects within a tree. It
Xis now time to go back and cure this omission.
X.PP
XThe technical term for the linkage scheme of an object tree is a
X"right-threaded binary tree".   If you already know what this is, you
Xcan skim over the next few paragraphs. If you happen to have access
Xto a copy of the book "FUNDAMENTAL ALGORITHMS", which is part of the
Xseries THE ART OF COMPUTER PROGRAMMING by Donald E. Knuth, you might
Xwant to read his excellent discussion of binary trees beginning on
Xpage 332.
X.PP
XFor the following discussion, you should have a listing of the C
Ximage of a resource tree in front of you. For those who do not have
Xthe listing from the last column, I have included a fragment at the
Xbeginning of the download. Before we begin, I should warn you of one
Xpeculiarity of "computer trees": They grow upside-down! That is,
Xwhen they are diagrammed or described, their root is at the top, and
Xthe "leaves" grow downward. You will see this both in the listing,
Xand in the way the following discussion talks about moving through
Xtrees.
X.PP
XEach GEM object tree begins at its ROOT object, numbered zero,
Xwhich is the object pointed at by the tree index. There are three
Xlink fields at the beginning of each object. They are called
XOB_NEXT, OB_HEAD, and OB_TAIL, which is the order in which they
Xappear.
X.PP
XEach of the links is shown as an index relative to the root of
Xthe current tree. This means that the link '0' would refer to the
Xroot of the tree, while '2' would indicate the object two lines below
Xit. The special link -1 is called NIL, and means that there is no
Xlink in the given direction.
X.PP
XEach object, or node, in a tree may have "offspring" or nodes
Xwhich are nested below it. If it does, then its OB_HEAD will point
Xto its first (or "leftmost") "child", while the OB_TAIL will point to
Xthe last ("rightmost") of its offspring. The OB_NEXT pointer links
Xthe children together, with the OB_NEXT of the first pointing to the
Xsecond, and so on, until the OB_NEXT of the last finally points back

Xto its parent, the object at which we started.
X.PP
XRemember that each of these children may in turn have offspring
Xof their own, so that the original "parent" may have a large and
Xcomplex collection of "descendents".
X.PP
XLet's look at the first tree in the download to see an example
Xof this structure. The very first object is the ROOT. Note that its
XOB_NEXT is NIL, meaning that there are no more objects in the tree:
Xthe ROOT is both the beginning and the end of the tree. In this
Xcase, the OB_HEAD is 1 and the OB_TAIL is 3, showing that there are
Xat least two different children.
X.PP
XFollowing OB_HEAD down to the next line, we can trace through
Xthe OB_NEXT links (2, 3, 0) as they lead through a total of three
Xchildren and back to the ROOT. You will notice that the first two
Xchildren have NIL for the OB_HEAD and OB_TAILs, indicating that they
Xhave no further offspring.
X.PP
XHowever, node three, the last child of the ROOT, does have the
Xvalue 4 for both its OB_HEAD and OB_TAIL. By this we can tell that
Xit has one, and only one, offspring. Sure enough, when we look at
Xnode four, we see that its OB_NEXT leads immediately back to node
Xthree. Additionally, it has no further offspring because its OB_HEAD
Xand OB_TAIL are NIL.
X.PP
XYou will find that object trees are always written out by the
XResource Construction Set in "pre-order". (Again, see Knuth if you
Xhave a copy.) This means that the ROOT is always written first, then
Xits offspring left to right. This rule is applied recursively, that
Xis, we go down to the next level and write out each of these nodes,
Xthen THEIR children left to right, and so on.
X.PP
XFor a further example, look at the next tree in rs_object in the
Xdownload. You will see that the ROOT has an OB_HEAD of 1 and an
XOB_TAIL of 6, but that it actually has only three offspring (nodes 1,
X2 and 6). We see that node 2 itself had children, and applying the
Xrule given above, they were written out before continuing with the
Xnext child of the ROOT.
X.PP
XWhy was this seemingly complex structure chosen for GEM? The
Xreason has do with the tasks of drawing objects in their proper
Xlocations on the screen, and determining which object was "hit" when
Xa mouse click is detected.
X.PP
XTo find out how this works, we must look at four more fields
Xfound in each object: OB_X, OB_Y, OB_WIDTH, and OB_HEIGHT. These
Xfields are the last four on each line in the sample trees.
X.PP
XEach object in a tree "owns" a rectangle on the screen. These
Xfields define that rectangle. When a resource is stored "outside"
Xthe program the fields are in character units, so that an object
Xwith OB_WIDTH of 10 and OB_HEIGHT of 2 (for instance) would define a

Xscreen area 10 characters wide and 2 high.
X.PP
XWhen the resource is read into memory with an rsrc_load call,
XGEM multiplies the appropriate character dimension in pixels into
Xeach of these fields. In this way portability is achieved: the same
Xresource file works for any of the ST's three resolutions. Knowing
Xhow rsrc_load works, your code should treat these fields as pixel
Xcoordinates.
X.PP
XI have committed one oversimplification above. If an object is
Xnot created on a character boundary in the RCS, then the external
Xstorage method described will not work. In this case, the lower byte
Xof each rectangle field is used to store the nearest character
Xposition, while the upper byte stores the pixel remainder to be added
Xafter the character size is multiplied in.
XNon-character-boundary objects may only be created in the "FREE"
Xtree mode of the Resource Construction Set (also called "PANEL" in
XRCS 2.0). You should use them only in programs which will run in a
Xsingle ST screen mode, because pixel coordinates are not portable
Xbetween resolutions.
X.PP
XThe first real secret of object rectangles is that each OB_X and
XOB_Y is specified RELATIVE to the X and Y coordinate of its parent
Xobject within the tree. This is the first property we have seen
Xthat is actually "inherited" from level to level within the tree.
X.PP
XThe second secret is more subtle: Every object's rectangle must
Xbe entirely contained within the rectangle of its parent. This
Xprinciple goes by the names "bounding rectangles" or "visual
Xhierarchy". We'll see in a moment how useful it is when detecting
Xmouse/object collisions.
X.SH HOW GEM DOES IT.
XKnowing these secrets, and the linkage structure of object
Xtrees, we can deduce how a number of the GEM operations must work.
XFor instance, consider objc_offset, which returns the actual screen
XX and Y of an object. We can see now that simply loading the OB_X
Xand OB_Y fields of the object does not suffice: they only give the
Xoffset relative to the parent object. So, objc_offset must BEGIN
Xwith these values, and then work its way back up to the ROOT of the
Xtree, adding in the offsets found at each level.
X.PP
XThis can be done by following the OB_NEXT links from the chosen
Xobject. Whenever OB_NEXT points to an object whose OB_TAIL points
Xright back to the same location, then the new node is another level,
Xor "parent" in the tree, and objc_offset adds its OB_X and OB_Y into
Xthe running totals. When OB_NEXT becomes NIL, then the ROOT has been
Xreached and the totals are the values to return. (By the way,
Xremember that the OB_X and OB_Y of the ROOT are undefined until
Xform_center has been called for the tree. They are shown as zeroes
Xin the sample trees.)
X.PP
XWe can also figure out objc_draw. It works its way DOWN the
Xtree, drawing each object as it comes to it. It, too, must keep a

Xrunning X and Y variable, adding in object offsets as it descends
Xtree levels (using OB_HEAD), and subtracting them again as it returns
Xfrom each level. Since the larger objects are nearer the ROOT, we
Xcan now see why they are drawn first, with smaller objects drawn
Xlater or "on top of" them.
X.PP
XIf you write an application which needs to move portions of a
Xdialog or screen with respect to each other, you can take advantage
Xof inheritance of screen position in objc_draw. Simply by changing
Xthe OB_X and/or OB_Y of an object, you can move it and its entire
Xsub-tree to a new location in the dialog. For instance, changing the
Xcoordinates of the parent box of a set of radio buttons will cause
Xall of the buttons to move along with it.
X.PP
XObjc_draw also gives us an example of the uses of visual
Xhierarchy. Recall that a clipping rectangle is specified when calling
Xobjc_draw. At each level of the tree we know that all objects below
Xare contained in the screen rectangle of the current object. If the
Xcurrent rectangle falls completely outside the specified clipping
Xrectangle, we know immediately that we need not draw the object, or
Xany of its descendents! This ability to ignore an entire subtree is
Xcalled "trivial rejection".
X.PP
XNow it's rather easy to figure out objc_find. It starts out by
Xsetting its "object found" variable to NIL. It begins a "walk"
Xthrough the entire object tree, following OB_HEAD and OB_NEXT links,
Xand keeping a current X and Y, just like objc_draw.
X.PP
XAt each node visited, it simply checks to see if the "mouse" X,Y
Xspecified in the call are inside the current object's rectangle. If
Xthey are, that object becomes the found object, and the tree walk
Xcontinues with the object's offspring, and then siblings. Notice how
Xthis checking of offspring makes sure that a smaller object nested
Xwithin, i.e., below, a larger object is found correctly.
X.PP
XIf the mouse X,Y position is not within the object being
Xchecked, then by visual hierarchy it cannot be within any of its
Xoffspring, either. Trivial rejection wins again, and the entire
Xsub-tree is skipped! Objc_find moves on to the OB_NEXT of the
Xrejected object.
X.SH THOUGHT EXPERIMENTS
XThinking about the objc_find algorithm reveals some information
Xabout its performance, and a few tricks we may use in improving the
Xappearance of dialogs and other object trees.
X.PP
XFirst consider the problem of a dialog which contains many
Xobjects. If we lay them all out "side-by-side", then they will all be
Ximmediate offspring of the ROOT object. In this situation, the
Xtrivial rejection method will gain nothing. The time objc_find takes
Xto complete will vary linearly with the total number of objects.
XThis is called an "Order N" process.
X.PP
XSuppose that instead we broke up the dialog into two areas with

Xinvisible boxes, then broke up each of these areas in a like fashion,
Xand so on until we got down to the size of the individual selectable
Xobjects. The number of bottom level objects in this scheme is a
Xpower of two equal to the depth of the tree. Trivial rejection is
Xused to its fullest in this case. It is called an "Order Log N"
Xprocess, and is much more efficient for large numbers of objects.
X.PP
XIn practice, the speed of the ST will allow you to ignore this
Xdistinction for most dialogs and other trees. But if you get into a
Xsituation when speed is critical in searching a large tree, remember
Xthat nesting objects can improve performance dramatically.
X.PP
XIf you have been following closely, you may have also noticed a
Xhole in the visual hierarchy rule. It says that all of a node's
Xchildren must lie within its rectangle, but it does NOT guarantee
Xthat the children's rectangles will be disjoint, that is, not
Xoverlap one another. This peculiarity is the basis of several useful
Xtricks.
X.PP
XFirst, remember that objc_find always tries to scan the entire
Xtree. That is, it doesn't quit when it finds the first object on the
Xgiven coordinates. As mentioned above, this normally guarantees that
Xnested objects will be found. Consider, however, what happens when
Xthe mouse coordinates are on a point where two or more objects AT
XTHE SAME LEVEL overlap: they will replace one another as the "found
Xobject" until objc_find returns with the one which is "last", that
Xis, rightmost in the tree.
X.PP
XThis quirk can be used to advantage in a number of cases.
XSuppose that you have in a dialog an image and a string which you
Xwould like to be selected together when either is clicked. Nesting
Xwithin a common parent achieves nothing in this case. Instead,
Xknowing that form_do must use objc_find, you could use our trick.
X.PP
XYou have to know that the Resource Construction Set normally
Xadds objects in a tree left to right, in the order in which you
Xinserted them. You proceed to build the dialog in the following
Xorder: insert the image first, the string next, then carefully add
Xan invisible box which is not nested within either, and size it to
Xcover them both. Set the SELECTABLE attribute for the box, and the
Xdialog manager will find it, and invert the whole area, when either
Xthe image or string is clicked.
X.PP
XBy the way, remember that the SORT option in the RCS will change
Xthe order of an object's offspring. If you are going to try this
Xtrick, don't use SORT! It will undo all of your careful work.
X.SH A TREEWALKER OF OUR OWN
XSince the GEM system gets so much mileage out of walking object
Xtrees, it seems reasonable that the same method should be useful in
Xapplication programs. In the download you will find map_tree(). As
Xmany LISP veterans might guess from the name, this code will traverse
Xall or part of an object tree, applying a function to each node. It
Xalso allows the function to return a true/false value specifying

Xwhether the sub-tree below a particular node should be ignored.
XLet's examine map_tree() in more detail as a final review of object
Xtree structure.
X.PP
XFirst, look at the parameters. "tree" is the long address of
Xthe object tree of interest, as retrieved by rsrc_gaddr. "this" is
Xthe node at which to begin the traverse, and "last" is the node at
Xwhich to terminate.
X.PP
XIn most cases, the beginning node will be ROOT, and the final
Xvalue will be NIL. This will result in the entire tree being
Xtraversed. You may use other values, but be sure that you CAN get to
X"last" from "this" by following tree links! Although map_tree()
Xincludes a safety check to prevent "running off" the tree, you could
Xget some very strange results from incorrect parameters.
X.PP
XThe declaration for the final parameter, "routine", makes use of
XC construct which may be new to some. It is a pointer to a
Xsubroutine which returns a WORD as a result.
X.PP
XMap_tree() begins by initializing a temporary variable, tmp1,
Xwhich is used to store the number of the last node visited. Since no
Xnode will follow itself, setting tmp1 to the starting node is safe.
X.PP
XThe main loop of the routine simply repeats visiting a new node
Xuntil the last value is reached, or the safety check for end of tree
Xis satisfied.
X.PP
XAt any node visited, we can be in one of two conditions. Either
Xwe are at a node which is "new", that is, not previously visited, or
Xelse we are returning to a parent node which has already been
Xprocessed. We can detect the latter condition by comparing the last
Xnode visited (tmp1) with the OB_TAIL pointer of the current node. If
Xthe node is "old", it is not processed a second time, we simply
Xupdate tmp1 and continue.
X.PP
XIf the node is new, we call "routine" to process it, sending the
Xtree address and object number as parameters. If a FALSE is
Xreturned, we will ignore any subtree below this node. On a TRUE
Xreturn, we load up the OB_HEAD pointer and follow it if a subtree
Xexists. (If you don't care about rejecting subtrees, simply remove
Xthe if condition.) Finally, if the new node had no subtree, or was
Xrejected by "routine", we follow along its OB_NEXT link to the next
Xnode.
X.PP
XA simple application of our new tool shows its power. From a
Xprevious column you may recall the tedium of deselecting every button
Xinside a dialog after it was completed. Using map_tree(), you can
Xdeselect EVERY OBJECT in the tree by using map_tree(tree, ROOT, NIL,
Xdesel_obj); You must use a slightly modified version of desel_obj()
X(included in the download) which always returns TRUE. Be sure to
Xdefine or declare desel_obj() in your code BEFORE making the map_tree
Xcall!

```
X.PP
XIn future columns, I will return to map_tree() and show how it
Xcan be used for advanced techniques such as animated dialogs.  In the
Xmeantime, experiment and enjoy!

X.PART VI Raster operations
X.SH SEASONS GREETINGS
XThis is the Yuletide installment of ST PRO GEM, devoted to
Xexplaining the raster, or "bit-blit" portion of the Atari ST's VDI
Xfunctions.
X.PP
XPlease note that this is NOT an attempt to show how to write
```

Xdirectly to the video memory, although you will be able to deduce a
Xgreat deal from the discussion.
X.PP
XAs usual, there is a download with this column. You will find
Xit in ATARI16 (PCS-58) in DL3 under the name of GEMCL6.C.
X.SH DEFINING TERMS
XTo understand VDI raster operations, you need to understand the
Xjargon used to describe them. (Many programmers will be tempted to
Xskip this section and go directly to the code. Please don't do it
Xthis time: Learning the jargon is the larger half of understanding
Xthe raster operations!)
X.PP
XIn VDI terms a raster area is simply a chunk of contiguous words
Xof memory, defining a bit image. This chunk is called a "form". A
Xform may reside in the ST's video map area or it may be in the data
Xarea of your application. Forms are roughly analogous to "blits" or
X"sprites" on other systems. (Note, however, that there is no sprite
Xhardware on the ST.)
X.PP
XUnlike other systems, there is NO predefined organization of the
Xraster form. Instead, you determine the internal layout of the form
Xwith an auxiliary data structure called the MFDB, or Memory Form
XDefinition Block. Before going into the details of the MFDB, we need
Xto look at the various format options. Their distinguishing features
Xare monochrome vs. color, standard vs. device-specific and even-word
Xvs. fringed.
X.SH MONOCHROME VS. COLOR
XAlthough these terms are standard, it might be better to say
X"single-color vs. multi-color". What we are actually defining is the
Xnumber of bits which correspond to each dot, or pixel, on the screen.
XIn the ST, there are three possible answers. The high-resolution mode
Xhas one bit per pixel, because there is only one "color": white.
X.PP
XIn the medium resolution color mode, there are four possible
Xcolors for each pixel. Therefore, it takes two bits to represent
Xeach dot on the screen. (The actual colors which appear are
Xdetermined by the settings of the ST's pallette registers.)
X.PP
XIn the low resolution color mode, sixteen colors are generated
Xrequiring four bits per pixel. Notice that as the number of bits per
Xpixel has been doubled for each mode, so the number of pixels on the
Xscreen has been halved: 640 by 400 for monochrome, 640 by 200 for
Xmedium-res, and 320 by 200 by low-res. In this way the ST always
Xuses the same amount of video RAM: 32K.
X.PP
XNow we have determined how many bits are needed for each pixel,
Xbut not how they are laid out within the form. To find this out, we
Xhave to see whether the form is device-dependent or not.
X.SH STANDARD VS. DEVICE-SPECIFIC FORMAT
XThe standard raster form format is a constant layout which is
Xthe same for all GEM systems. A device-specific form is one which is
Xstored in the internal format of a particular GEM system. Just as
Xthe ST has three different screen modes, so it has three different

Xdevice-specific form formats. We will look at standard form first,
Xthen the ST-specific forms.
X.PP
XFirst, it's reasonable to ask why a standard format is used. Its
Xmain function is to establish a portability method between various
XGEM systems. For instance, an icon created in standard format on an
XIBM PC GEM setup can be moved to the ST, or a GEM Paint picture from
Xan AT&T 6300 could be loaded into the ST version of Paint.
X.PP
XThe standard format has some uses even if you only work with the
XST, because it gives a method of moving your application's icons and
Ximages amongst the three different screen modes. To be sure, there
Xare limits to this. Since there are different numbers of pixels in
Xthe different modes, an icon built in the high-resolution mode will
Xappear twice as large in low-res mode, and would appear oblong in
Xmedium-res. (You can see this effect in the ST Desktop's icons.)
XAlso, colors defined in the lower resolutions will be useless in
Xmonochrome.
X.PP
XThe standard monochrome format uses a one-bit to represent
Xblack, and uses a zero for white. It is assumed that the form begins
Xat the upper left of the raster area, and is written a word at a
Xtime left to right on each row, with the rows being output top to
Xbottom. Within each word, the most significant bit is the left-most
Xon the screen.
X.PP
XThe standard color form uses a storage method called "color
Xplanes". The high-order bits for all of the pixels are stored just as
Xfor monochrome, followed by the next-lowest bit in another contiguous
Xblock, and so on until all of the necessary color bits have been
Xstored.
X.PP
XFor example, on a 16-color system, there would be four different
Xplanes. The color of the upper-leftmost bit in the form would be
Xdetermined by concatenating the high-order bit in the first word of
Xeach plane of the form.
X.PP
XThe system dependent form for the ST's monochrome mode is very
Xsimple: it is identical to the standard form! This occurs because
Xthe ST uses a "reverse-video" setup in monochrome mode, with the
Xbackground set to white.
X.PP
XThe video organization of the ST's color modes is more
Xcomplicated. It uses an "interleaved plane" system to store the bits
Xwhich make up a pixel. In the low-resolution mode, every four words
Xdefine the values of 16 pixels. The high-order bits of the four
Xwords are merged to form the left-most pixel, followed by the next
Xlower bit of each word, and so on. This method is called
Xinterleaving because the usually separate color planes described
Xabove have been shuffled together in memory.
X.PP
XThe organization of the ST's medium-resolution mode is similar
Xto low-res, except the only two words are taken at a time. These are

Xmerged to create the two bits needed to address four colors.
X.PP
XYou should note that the actual color produced by a particular
Xpixel value is NOT fixed. The ST uses a color remapping system
Xcalled a palette. The pixel value in memory is used to address a
Xhardware register in the palette which contains the actual RGB
Xlevels to be sent to the display. Programs may set the palette
Xregisters with BIOS calls, or the user may alter its settings with
Xthe Control Panel desk accessory. Generally, palette zero
X(background) is left as white, and the highest numbered palette is
Xblack.
X.SH EVEN-WORD VS. FRINGES
XA form always begins on a word boundary, and is always stored
Xwith an integral number of words per row. However, it is possible
Xto use only a portion of the final word. This partial word is called
Xa "fringe". If, for instance, you had a form 40 pixels wide, it
Xwould be stored with four words per row: three whole words, and one
Xword with the eight pixel fringe in its upper byte.
X.SH MFDB's
XNow we can intelligently define the elements of the MFDB. Its
Xexact C structure definition will be found in the download. The
Xfd_nplanes entry determines the color scheme: a value of one is
Xmonochrome, more than one denotes a color form. If fd_stand is zero,
Xthen the form is device-specific, otherwise it is in standard format.
X.PP
XThe fd_w and fd_h fields contain the pixel width and height of
Xthe form respectively. Fd_wdwidth is the width of a row in words.
XIf fd_w is not exactly equal to sixteen times fd_wdwidth, then the
Xform has a fringe.
X.PP
XFinally, fd_addr is the 32-bit memory address of the form
Xitself. Zero is a special value for fd_addr. It denotes that this
XMFDB is for the video memory itself. In this case, the VDI
Xsubstitutes the actual address of the screen, and it ignores ALL of
Xthe other parameters. They are replaced with the size of the whole
Xscreen and number of planes in the current mode, and the form is (of
Xcourse) in device-specific format.
X.PP
XThis implies that any MFDB which points at the screen can only
Xaddress the entire screen. This is not a problem, however, since the
Xthe VDI raster calls allow you to select a rectangular region within
Xthe form. (A note to advanced programmers: If this situation is
Xannoying, you can retrieve the address of the ST's video area from
Xlow memory, add an appropriate offset, and substitute it into the
XMFDB yourself to address a portion of the screen.)
X.SH LET'S OPERATE
XNow we can look at the VDI raster operations themselves. There
Xare actually three: transform form, copy raster opaque, and copy
Xraster transparent. Both copy raster functions can perform a variety
Xof logic operatoins during the copy.
X.SH TRANSFORM FORM
XThe purpose of this operation is to change the format of a form:
Xfrom standard to device-specific, or vice-versa. The calling

Xsequence is:
X.FB vr_trnfm()
Xvr_trnfm(vdi_handle, source, dest);
X.FE
Xwhere source and dest are each pointers to MFDBs. They ARE allowed
Xto be the same. Transform form checks the fd_stand flag in the
Xsource MFDB, toggles it and writes it into the destination MFDB after
Xrewriting the form itself. Note that transform form CANNOT change
Xthe number of color planes in a form: fd_nplanes must be identical in
Xthe two MFDBs.
X.PP
XIf you are writing an application to run on the ST only, you
Xwill probably be able to avoid transform form entirely. Images and
Xicons are stored within resources as standard forms, but since they
Xare monochrome, they will work "as is" with the ST.
X.PP
XIf you may want to move your program or picture files to another
XGEM system, then you will need transform form. Screen images can be
Xtransformed to standard format and stored to disk. Another system
Xwith the same number of color planes could the read the files, and
Xtransform the image to ITS internal format with transform form.
X.PP
XA GEM application which will be moved to other systems needs to
Xcontain code to transform the images and icons within its resource,
Xsince standard and device-specific formats will not always coincide.
X.PP
XIf you are in this situation, you will find several utilities in
Xthe download which you can use to transform G_ICON and G_IMAGE
Xobjects. There is also a routine which may be used with map_tree()
Xfrom the last column in order to transform all of the images and
Xicons in a resource tree at once.
X.SH COPY RASTER OPAQUE
XThis operation copies all or part of the source form into the
Xdestination form. Both the source and destination forms must be in
Xdevice-specific form. Copy raster opaque is for moving information
Xbetween "like" forms, that is, it can copy from monochrome to
Xmonochrome, or between color forms with the same number of planes.
XThe calling format is:
X.FB vro_cpyfm()
Xvro_cpyfm(vdi_handle, mode, pxy, source, dest);
X.FE
XAs above, the source and dest parameters are pointers to MFDBs
X(which in turn point to the actual forms). The two MFDBs may point
Xto memory areas which overlap. In this case, the VDI will perform
Xthe move in a non-destructive order. Mode determines how the pixel
Xvalues in the source and destination areas will be combined. I will
Xdiscuss it separately later on.
X.PP
XThe pxy parameter is a pointer to an eight-word integer array.
XThis array defines the area within each form which will be affected.
XPxy[0] and pxy[1] contain, respectively, the X and Y coordinates of
Xthe upper left corner of the source rectangle. These are given as
Xpositive pixel displacements from the upper left of the form.

XPxy[2] and pxy[3] contain the X and Y displacements for the lower
Xright of the source rectangle.
X.PP
XPxy[4] through pxy[7] contain the destination rectangle in the
Xsame format. Normally, the destination and source should be the same
Xsize. If not, the size given for the source rules, and the whole are
Xis transferred beginning at the upper left given for the destination.
X.PP
XThis all sounds complex, but is quite simple in many cases.
XConsider an example where you want to move a 32 by 32 pixel area
Xfrom one part of the display to another. You would need to allocate
Xonly one MFDB, with a zero in the fd_addr field. The VDI will take
Xcare of counting color planes and so on. The upper left raster
Xcoordinates of the source and destination rectangles go into pxy[0],
Xpxy[1] and pxy[4], pxy[5] respectively. You add 32 to each of these
Xvalues and insert the results in the corresponding lower right
Xentries, then make the copy call using the same MFDB for both source
Xand destination. The VDI takes care of any overlaps.
X.SH COPY RASTER TRANSPARENT
XThis operation is used for copying from a monochrome form to a
Xcolor form. It is called transparent because it "writes through" to
Xall of the color planes. Again, the forms need to be in
Xdevice-specific form. The calling format is:
X.FB vrt_cpyfm()
Xvrt_cpyfm(vdi_handle, mode, pxy, source, dest, color);
X.FE
XAll of the parameters are the same as copy opaque, except that
Xcolor has been added. Color is a pointer to a two word integer
Xarray. Color[0] contains the color index which will be used when a
Xone appears in the source form, and color[1] contains the index for
Xuse when a zero occurs.
X.PP
XIncidentally, copy transparent is used by the AES to draw
XG_ICONs and G_IMAGEs onto the screen. This explains why you do not
Xneed to convert them to color forms yourself.
X.PP
XA note for advanced VDI programmers: The pxy parameter in both
Xcopy opaque and transparent may be given in normalized device
Xcoordinates (NDC) if the workstation associated with vdi_handle was
Xopened for NDC work.
X.SH THE MODE PARAMETER
XThe mode variable used in both of the copy functions is an
Xinteger with a value between zero and fifteen. It is used to select
Xhow the copy function will merge the pixel values of the source and
Xdestination forms. The complete table of functions is given in the
Xdownload. Since a number of these are of obscure or questionable
Xusefulness, I will only discuss the most commonly used modes.
X.SH REPLACE MODE
XA mode of 3 results in a straight-forward copy: every
Xdestination pixel is replaced with the corresponding source form
Xvalue.
X.SH ERASE MODE
XA mode value of 4 will erase every destination pixel which

Xcorresponds to a one in the source form. (This mode corresponds to
Xthe "eraser" in a Paint program.) A mode value of 1 will erase every
Xdestination pixel which DOES NOT correspond to a one in the source.
X.SH XOR MODE
XA mode value of 6 will cause the destination pixel to be toggled
Xif the corresponding source bit is a one. This operation is
Xinvertable, that is, executing it again will reverse the effects.
XFor this reason it is often used for "software sprites" which must be
Xshown and then removed from the screens. There are some problems
Xwith this in color operations, though - see below.
X.SH TRANSPARENT MODE
XDon't confuse this term with the copy transparent function
Xitself. In this case it simply means that ONLY those destination
Xpixels corresponding with ones in the source form will be modified
Xby the operation. If a copy transparent is being performed, the
Xvalue of color[0] is substituted for each one bit in the source form.
XA mode value of 7 selects transparent mode.
X.SH REVERSE TRANSPARENT MODE
XThis is like transparent mode except that only those destination
Xpixels corresponding to source ZEROS are modified. In a copy
Xtransparent, the value of color[1] is substituted for each zero bit.
XMode 13 selects reverse transparent.
X.SH THE PROBLEM OF COLOR
XI have discussed the various modes as if they deal with one and
Xzero pixel values only. This is exactly true when both forms are
Xmonochrome, but is more complex when one or both are color forms.
X.PP
XWhen both forms are color, indicating that a copy opaque is
Xbeing performed, then the color planes are combined bit-by-bit using
Xthe rule for that mode. That is, for each corresponding source and
Xdestination pixel, the VDI extracts the top order bits and processes
Xthem, then operates on the next lower bit, and so on, stuffing each
Xbit back into the destination form as the copy progresses. For
Xexample, an XOR operation on pixels valued 7 and 10 would result in a
Xpixel value of 13.
X.PP
XIn the case of a copy transparent, the situation is more
Xcomplex. The source form consists of one plane, and the destination
Xform has two or more. In order to match these up, the color[] array
Xis used. Whenever a one pixel is found, the value of color[0] is
Xextracted and used in the bit-by-bit merge process described in the
Xlast paragraph. When a zero is found, the value of color[1] is
Xmerged into the destination form.
X.PP
XAs you can probably see, a raster copy using a mode which
Xcombines the source and destination can be quite complex when color
Xplanes are used! The situation is compounded on the ST, since the
Xactual color values may be remapped by the palette at any time.   In
Xmany cases, just using black and white in color[] may achieve the
Xeffects you desire. If need to use full color, experimentation is
Xthe best guide to what looks good on the screen and what is garish
Xor illegible.
X.SH OPTIMIZING RASTER OPERATIONS

XBecause the VDI raster functions are extremely generalized, they
Xare also slower than hand-coded screen drivers which you might write
Xfor your own special cases. If you want to speed up your
Xapplication's raster operations without writing assembl language
Xdrivers, the following hints will help you increase the VDI's
Xperformance.
X.SH AVOID MERGED COPIES
XThese are copy modes, such as XOR, which require that words be
Xread from the destination form. This extra memory access increases
Xthe running time by up to fifty percent.
X.SH MOVE TO CORRESPONDING PIXELS
XThe bit position within a word of the destination rectangle
Xshould correspond with the bit position of the source rectangle's
Xleft edge. For instance, if the source's left edge is one pixel in,
Xthen the destination's edge could be at one, seventeen, thirty-three,
Xand so. Copies which do not obey this rule force the VDI to shift
Xeach word of the form as it is moved.
X.SH AVOID FRINGES
XPut the left edge of the source and destination rectangles on
Xan even word boundary, and make their widths even multiples of
Xsixteen. The VDI then does not have to load and modify partial words
Xwithin the destination forms.
X.SH USE ANOTHER METHOD
XSometimes a raster operation is not the fastest way to
Xaccomplish your task. For instance, filling a rectangle with zeros
Xor ones may be accomplished by using raster copy modes zero and
Xfifteen, but it is faster to use the VDI v_bar function instead.
XLikewise, inverting an area on the screen may be done more quickly
Xwith v_bar by using BLACK in XOR mode. Unfortunately, v_bar cannot
Xaffect memory which is not in the video map, so these alternatives
Xdo not always work.
X.SH FEEDBACK RESULTS
XThe results of the poll on keeping or dropping the use of
Xportability macros are in. By a slim margin, you have voted to keep
Xthem. The vote was close enough that in future columns I will try to
Xinclude ST-only versions of routines which make heavy use of the
Xmacros. C purists and dedicated Atarians may then use the alternate
Xcode.
X.SH THE NEXT QUESTION
XThis time I'd like to ask you to drop by the Feedback Section
Xand tell me whether the technical level of the columns has been:
X.br
X.sp 1
X.in +4
XA) Too hard! Who do you think we are, anyway?
X.br
XB) Too easy! Don't underestimate Atarians.
X.br
XC) About right, on the average.
X.in -4
X.PP
XIf you have the time, it would also help to know a little about
Xyour background, for instance, whether you are a professional

```
Xprogrammer, how long you have been computing, if you owned an 8-bit
XAtari, and so on.
X.SH COMING UP SOON
XThe next column will deal with GEM menus: How they are
Xconstructed, how to decipher menu messages, and how to change menu
Xentries at run-time.  The following issue will contain more feedback
Xresponse, and a discussion on designing user interfaces for GEM
Xprograms.

X.PART VII Menu Structures
X.SH HAPPY NEW YEAR
XThis is article number seven in the ST
XPRO GEM series, and the first for 1986.  In this installment,
XI will be discussing GEM menu structures and how to use them
Xin your application.  There is  also a short Feedback
Xresponse section.  You will find the download file containing
Xthe code for this column in the file GEMCL7.C in DL3 of the
XATARI16 SIG (PCS-58).
X.SH MENU BASICS
XIn ST GEM, the menu consists of a bar
Xacross the top of the screen which displays several sub-menu
Xtitles.  Touching one of the titles causes it to highlight,
Xand an associated "drop-down" to be drawn  directly below on
Xthe screen.  This drop-down may be dismissed by moving  to
```

Xanother title, or by clicking the mouse off of the drop-down.
X.PP
XTo make a selection, the mouse is moved over the
Xdrop-down. Each valid selection is highlighted when the
Xmouse touches it. Clicking the mouse while over one of
Xthese selections picks that item. GEM then undraws the
Xdrop-down, and sends a message to your application giving the
Xobject number of the title bar entry, and the object number
Xof the drop-down item which were selected by the user. The
Xselected title entry is left highlighted while your code
Xprocesses the request.
X.SH MENU STRUCTURES
XThe data structure which defines a GEM
Xmenu is (surprise!) an object tree, just like the dialogs and
Xpanels which we have discussed before. However, the
Xoperations of the GEM menu manager are quite different from
Xthose of the form manager, so the internal design of the menu
Xtree has some curious constraints.
X.PP
XThe best way to understand these constraints is to look
Xat an example. The first item in the download is the object
Xstructure (only) of the menu tree from the GEM Doodle/Demo
Xsample application.
X.PP
XThe ROOT of a menu tree is sized to fit the entire
Xscreen. To satisfy the visual hierarchy principle (see
Xarticle #5), the screen is divided into two parts: THE BAR,
Xcontaining the menu titles, and THE SCREEN, while contains
Xthe drop-downs when they are drawn. Each of these areas is
Xdefined by an object of the same name, which are the only two
Xobjects linked directly below the ROOT of a menu tree. You
Xwill notice an important implication of this structure: The
Xmenu titles and their associated drop-downs are stored in
Xentirely different subtrees of the menu!
X.PP
XWhile examining THE BAR in the example listing, you may
Xnotice that its OB_HEIGHT is very large (513). In
Xhexadecimal this is 0x0201. This defines a height for THE
XBAR of one character plus two pixels used for spacing. THE
XBAR and its subtree are the only objects which are drawn on
Xthe screen in the menu's quiescent state.
X.PP
XThe only offspring object of THE BAR is THE ACTIVE. This
Xobject defines the part of THE BAR which is covered by menu
Xtitles. The screen rectangle belonging to THE ACTIVE is used
Xby the GEM screen manager when it waits for the mouse to
Xenter an active menu title. Notice that THE ACTIVE and its
Xoffspring also have OB_HEIGHTs with pixel residues.
X.PP
XThe actual menu titles are linked left to right in order
Xbelow THE ACTIVE. Their OB_Xs and OB_WIDTHs are arranged so
Xthat they completely cover THE ACTIVE. Normally, the title
Xobjects are typed G_TITLE, a special type which assures that

Xthe title bar margins are correctly drawn.
X.PP
XTHE SCREEN is the parent object of the drop-down boxes
Xthemselves. They are linked left to right in an order
Xidentical with their titles, so that the menu manager can
Xmake the correct correspondence at run-time. The OB_X of
Xeach drop-down is set so that it is positioned below its
Xtitle on the screen.
X.PP
XNotice that it is safe to overlap the drop-downs within a
Xmenu, since only one of them will be displayed at any time.
XThere is one constraint on the boxes however: They must be
Xno greater than a quarter screen in total size. This is the
Xsize of the off-screen blit buffer which is used by GEM to
Xstore the screen contents when the drop-down is drawn. If
Xyou exceed this size, not all the screen under the drop-down
Xwill be restored, or the ST may crash!
X.PP
XThe entries within a drop-down are usually G_STRINGs,
Xwhich are optimized for drawing speed. The rectangles of
Xthese entries must completely cover the drop-down, or the
Xentire drop-down will be inverted when the mouse touches an
Xuncovered area! Techniques for using objects other than
XG_STRINGs are discussed later in this column.
X.PP
XThe first title and its corresponding drop-down are
Xspecial. The title name, by custom, is set to DESK. The
Xdrop-down must contain exactly eight G_STRING objects. The
Xfirst (again by custom) is the INFO entry, which usually
Xleads to a dialog displaying author and copyright information
Xfor your application. The next is a separator string of
Xdashes with the DISABLED flag set. The following six objects
Xare dummy strings which GEM fills in with the names of desk
Xaccessories when your menu is loaded.
X.PP
XThe purpose of this description of menu trees is to give
Xyou an understanding of what lies "behind the scenes" in the
Xnext section, which describes the run-time menu library
Xcalls. In practice, the Resource Construction Set provides
X"blank menus" which include all of the required elements, and
Xit also enforces the constraints on internal structure. You
Xonly need to worry about these if you modify the menu tree
X"on-the-fly".
X.SH USING THE MENU
Xonce you have loaded the application's
Xresource, you can ask the AES to install your menu. You must
Xfirst get the address of the menu tree within the resource
Xusing:
X.FB rsrc_gaddr()
Xrsrc_gaddr(R_TREE, MENUTREE, &ad_menu);
X.FE
Xassuming that MENUTREE is the name you gave the menu in the
XRCS, and that ad_menu is a LONG which will receive the

Xaddress. Then you call the AES to establish the menu:
X.FB menu_bar()
Xmenu_bar(ad_menu, TRUE);
X.FE
XAt this point, the AES draws your menu bar on the screen and
Xanimates it when the user moves the mouse into the title
Xarea.
X.PP
XThe AES indicates that the user has made a menu selection
Xby sending your application a message. The message type is
XMN_SELECTED, which will be stored in msg[0], the first
Xlocation in the message returned by evnt_multi().
X.PP
XThe AES also stores the object number of the selected
Xmenu's title in msg[3], and the object number of the
Xselected menu item in msg[4]. Generally, your application
Xwill process menu messages with nested C switch statements.
XThe outer switch will have one case for each menu title, and
Xthe inner switch statements will have a case for each entry
Xwithin the selected menu. (This implies that you must give a
Xname to each title and to each menu entry when you create the
Xmenu in the RCS.)
X.PP
XAfter the user has made a menu selection, the AES leaves
Xthe title of the chosen menu in reverse video to indicate
Xthat your application is busy processing the message. When
Xyou done with whatever action is indicated, you need to
Xreturn the title to a normal state. This is done with
X.FB menu_tnormal()
Xmenu_tnormal(ad_menu, msg[3], TRUE);
X.FE
X.sp 1
X.ce 1
X(Remember that msg[3] is the title's object number.)
X.sp 1
XWhen your application is ready to terminate, it should
Xdelete its menu bar. Do this with the call:
Xmenu_bar(ad_menu, FALSE);
X.SH GETTING FANCY
XThe techniques above represent the bare
Xminimum to handle menus. In most cases, however, you will
Xwant your menus to be more "intelligent" in displaying the
Xuser's options. For instance, you can prevent many user
Xerrors by disabling inappropriate choices, or you can save
Xspace on drop-downs by showing only one line for a toggle and
Xaltering its text or placing and removing a check mark when
Xthe state is changed. This section discusses these and other
Xadvanced techniques.
X.PP
XIt is a truism of user interface design that the best way
Xto deal with an error is not to let it happen in the first
Xplace. It many cases, you can apply this principle to GEM
Xmenus by disabling choices which should not be used. If

Xyour application uses a "selection precedes action" type of
Xinterface, the type of object selected may give the
Xinformation needed to do this.   Alternately, the state of
Xthe underlying program may render certain menu choices
Xillegal.
X.PP
XGEM provides a call to disable and re-enable menu
Xoptions. The call is:
X.FB menu_ienable()
Xmenu_ienable(ad_menu, ENTRY, FALSE);
X.FE
Xto disable a selection. The entry will be grayed out when
Xit is drawn, and will not invert under the mouse and will not
Xbe selected by the user. Substituting TRUE for FALSE
Xre-enables the option. ENTRY is the name of the object
Xwhich is being affected, as assigned in the RCS.
X.PP
XNote that menu_ienable() will not normally affect the
Xappearance or operation of menu TITLE entries. However,
Xthere is an undocumented feature which allows this. If ENTRY
Xis replaced by the object number of a title bar entry with
Xits top bit set, then the entire associated drop-down will be
Xdisabled or re-enabled as requested, and the title's
Xappearance will be changed. But, be warned that this feature
Xdid not work reliably in some early versions of GEM. Test it
Xon your copy of ST GEM, and use it with caution when you
Xcannot control the version under which your application may
Xrun.
X.PP
XIt is also possible to disable menu entries by directly
Xaltering the DISABLED attribute within the OB_STATE word.
XThe routines enab_obj() and disab_obj() in the download show
Xhow this is done. They are also used in set_menu(), which
Xfollows them immediately.
X.PP
XSet_menu() is a utility which is useful when you wish to
Xsimultaneously enable or disable many entries in the menu
Xwhen the program's state changes or a new object is selected
Xby the user.   It is called with
X.FB set_menu()
Xset_menu(ad_menu, vector);
X.FE
Xwhere vector is a pointer to an array of WORDs. The first
Xword of the array determines the default state of menu
Xentries. If it is TRUE, then set_menu() enables all entries
Xin every drop-down of the menu tree, except that the DESK
Xdrop-down is unaffected. If it is FALSE, then every menu
Xentry is disabled.
X.PP
XThe following entries in the array are the numbers of
Xmenu entries which are to be toggled to the reverse of the
Xdefault state. This list is terminated by a zero entry.
X.PP

XThe advantage of set_menu() is that it allows you to
Xbuild a collection of menu state arrays, and associate one
Xwith each type of user-selected object, program state, and so
Xon. Changing the status of the menu tree may then be
Xaccomplished with a single call.
X.SH CHECK, PLEASE?
XOne type of state indicator which may
Xappear within a drop-down is a checkmark next to an entry.
XYou can add the checkmark with the call:
X.FB menu_icheck()
Xmenu_icheck(ad_menu, ENTRY, TRUE);
X.FE
Xand remove it by replacing the TRUE with FALSE. As above,
XENTRY is the name of the menu entry of interest. The
Xcheckmark appears inside the left boundary of the entry
Xobject, so leave some space for it.
X.PP
XThe menu_icheck() call is actually changing the state of
Xthe CHECKED flag within the entry object's OB_STATE word. If
Xnecessary, you may alter the flag directly using do_obj() and
Xundo_obj() from the download.
X.SH NOW YOU SEE IT, NOW YOU DON'T
XYou can also alter the
Xtext which appears in a particular menu entry (assuming that
Xthe entry is a G_STRING object). The call
X.FB menu_text()
Xmenu_text(ad_menu, ENTRY, ADDR(text));
X.FE
Xwill substitute the null-terminated string pointed to by
Xtext for whatever is currently in ENTRY. Remember to make
Xthe drop-down wide enough to handle the largest text string
Xwhich you may substitute. In the interests of speed,
XG_STRINGs drawn within drop-downs are not clipped, so you may
Xget garbage characters on the desktop if you do not size the
Xdrop-down properly!
X.PP
XThe menu_text() call actually alters the OB_SPEC field of
Xthe menu entry object to point to the string which you
Xspecify. Since the menu tree is a static data structure
Xwhich may be directly accessed by the AES at any time, be
Xsure that the string is also statically allocated and that it
Xis not modified without first being delinked from the menu
Xtree. Failure to do this may result in random crashes when
Xthe user accesses the drop-down!
X.SH LUNCH AND DINNER MENUS
XSome applications may have such
Xa wide range of operations that they need more than one menu
Xbar at different times. There is no problem with having
Xmore than one menu tree in a resource, but the AES can only
Xkeep track of one at a time. Therefore, to switch menus you
Xneed to use menu_bar(ad_menu1, FALSE); to release the first
Xmenu, then use menu_bar(ad_menu2, TRUE); to load the second
Xmenu tree.

X.PP
XChanging the entire menu is a drastic action. Out of
Xconsideration for your user, it should be associated with
Xsome equally obvious change in the application which has just
Xbeen manually requested. An example might be changing from
Xspreadsheet to data graphing mode in a multi-function
Xprogram.
X.SH DO IT YOURSELF
XIn a future column, I will discuss how
Xto set up user-defined drawing objects. If you have already
Xdiscovered them on your own, you can use them within a
Xdrop-down or as a title entry.
X.PP
XIf the user-defined object is within a drop-down, its
Xassociated drawing code will be called once when the
Xdrop-down is first drawn. It will then be called in
X"state-change" mode when the entry is highlighted (inverted).
XThis allows you to use non-standard methods to show
Xselection, such as outlines.
X.PP
XIf you try to insert a user-defined object within the
Xmenu title area, remember that the G_TITLE object which you
Xare replacing includes part of the dark margin of the bar.
XYou will need to experiment with your object drawing code to
Xreplicate this effect.
X.SH MAKE PRETTY
XThere are a number of menu formatting
Xconventions which have become standard practice. Using these
Xgives your application a recognizable "look-and-feel" and
Xhelps users learn it. The following section reviews these
Xconventions, and supplies a few hints and tricks to obtain a
Xbetter appearance for you menus.
X.PP
XThe second drop-down is customarily used as the FILE
Xmenu. It contains options related to loading and saving the
Xfiles used by the application, as well as entries for
Xclearing the workspace and terminating the program.
X.PP
XYou should avoid crowding the menu bar. Leave a couple
Xof spaces between each entry, and try not to use more than
X70% of the bar. Not only does this look better, but you will
Xhave space for longer words if you translate your application
Xto a foreign language.
X.PP
XSimilarly, avoid cluttering menu drop-downs. Try to keep
Xthe number of options to no more than ten unless they are
Xclearly related, such as colors. Separate off dissimilar
Xentries with the standard disabled dashes line. (If you are
Xusing set_menu(), remember to consider the separators when
Xsetting up the state vectors.)
X.PP
XIf the number of options grows beyond this bound, it may
Xbe time to move them to a dialog box. If so, it is a

```
Xconvention to put three dots following each menu entry which
Xleads to a dialog. Also, allow a margin on the menu entries.
XTwo leading blanks and a minimum of one trailing blank is
Xstandard, and allows room for checkmarks if they are used.
X.PP
XDangerous menu options should be far away from common
Xused entries, and are best separated with dashed lines.  Such
Xoptions should either lead to a confirming go/no-go alert, or
Xshould have associated "undo" options.
X.PP
XAfter you have finished defining a menu drop-down with
Xthe RCS,  be sure that its entries cover the entire box.
XThen use ctrl-click to  select the drop-down itself, and SORT
Xthe entries top to bottom.  This  way the drop-down draws in
Xsmoothly top to bottom.
X.PP
XFinally, it is possible to put entries other than
XG_STRINGs into drop-downs.  In the RCS, you will need to
Ximport them via the clipboard from the Dialog mode.
X.PP
XSome non-string object, such as icons and images, will
Xlook odd  when they are inverted under the mouse.  There is a
Xstandard trick for  dealing with this problem.  Insert the
Xicon or whatever in the drop-down first.  Then get a G_IBOX
Xobject and position and size it so that it covers the first
Xobject as well as the extra area you would like to be
Xinverted.
X.PP
XEdit the G_IBOX to remove its border, and assign the
Xentry name  to it.  Since the menu manager uses objc_find(),
Xit will detect and invert this second object when the mouse
Xmoves into the drop-down.  (To see why, refer to article #5.)
XFinally, DO NOT SORT a drop-down which has been set  up this
Xway!
X.SH  THAT'S IT FOR NOW!
XThe next column will discuss some of
Xthe principles of designing GEM interfaces for applications.
XThis topic is irreverantly known as GEM mythology or
Xinterface religion.  The subject for the following column is
Xundecided.  I am considering mouse and keyboard messages, VDI
Xdrawing primitives, and the file selector as topics.  Let me
Xknow your preferences in the Feedback!

X.PART VIII  USER INTERFACES
X.SH AND NOW FOR SOMETHING COMPLETELY DIFFERENT!
XIn response to a
Xnumber of requests, this installment of ST PRO GEM will be devoted
Xto examining a few of the principles of computer/human interface
Xdesign, or "religion" as some would have it.  I'm going to start
Xwith basic ergonomic laws, and try to draw some conclusions which
Xare fairly specific to designing for the ST.  If this article
Xmeets with general approval, further "homilies" may appear at
Xirregular intervals as part of the ST PRO GEM series.
X.PP
XFor those who did NOT ask for this topic, it seems fair to
Xexplain why your diet of hard-core technical information has been
Xinterrupted by a sermon!  As a motivater, we might consider why
Xsome programs are said by reviewers to have a "hot" feel (and
Xhence sell well!) while others are "confusing" or "boring".
X.PP
XAlan Kay has said that "user interface is theatre".  I think
Xwe may be able to take it further, and suggest that a successful
Xprogram works a bit of magic, persuading the user to suspend his
Xdisbelief and enter an imaginary world behind the screen, whether
Xit is the mathematical world of a spreadsheet, or the land of Pacman
```

```
Xpursued by ghosts.
X.PP
XA reader of a novel or science fiction story also suspends
Xdisbelief to participate in the work.  Bad grammar and clumsy plotting
Xby the author are jarring, and break down the illusion.  Similarly,
Xa programmer who fails to pay attention to making his interface
Xfast and consistent will annoy the user, and distract him from
Xwhatever care has been lavished on the functional core of the program.
X.SH CREDIT WHERE IT'S DUE
XBefore launching into the discussion
Xof user interface, I should mention that the general treatment and
Xmany of the specific research results are drawn from Card, Newell,
Xand Moran's landmark book on the topic, which is cited at the end
Xof the article.  Any errors in interpretation and application to
XGEM and the ST are entirely my own, however.
X.SH FINGERTIPS
XWe'll start right at the user's fingers with the
Xbasic equation governing positioning of the mouse, Fitt's Law,
Xwhich is given as
X.sp 1
X.ce 1
XT = I * LOG2( D / S + .5)
X.sp 1
Xwhere T is the amount of time to move to a target, D is the distance
Xof the target from the current position, and S is the size of the
Xtarget, stated in equivalent units.  LOG2 is the base 2 (binary)
Xlogarithm function, and I is a proportionality constant, about
X100 milliseconds per bit, which corresponds to the human's "clock
Xrate" for making incremental movements.
X.PP
XWe can squeeze an amazing amount of information out of this
Xformula when attempting to speed up an interface.  Since motion time
Xgoes up with distance, we should arrange the screen with the
Xusual working area near the center, so the mouse will have to move
Xa smaller distance on average from a selected object to a menu or
Xpanel.  Likewise, any items which are usually used together should
Xbe placed together.
X.PP
XThe most common operations will have the greater impact on
Xspeed, so they should be closest to the working area and perhaps
Xlarger than other icons or menu entries.  If you want to have
Xall other operations take about the same time, then the targets
Xfarthest from the working area should be larger, and those closer
Xmay be proportionately smaller.
X.PP
XConsider also the implications for dialogs.  Small check boxes
Xare out.  Large buttons which are easy to hit are in.  There should
Xbe ample space between selectable items to allow for positioning
Xerror.  Dangerous options should be widely separated from common
Xselections.
X.SH MUSCLES
XAnyone who has used the ST Desktop for any period
Xof time has probably noticed that his fingers now know where to find
```

Xthe File menu. This phenomenon is sometimes called "muscle memory",
Xand its rate of onset is given by the Power Law of Practice:
X.sp 1
X.ce 1
XT(n) = T(1) * n ** (-a)
X.sp 1
Xwhere T(n) is the time on the nth trial, T(1) is the time on the
Xfirst trial, and a is approximately 0.4. (I have appropriated
X** from Fortran as an exponentiation operator, since C lacks one.)
X.PP
XThis first thing to note about the Power Law is that it only
Xworks if a target stays in the same place! This should be a potent
Xargument against rearranging icons, menus, or dialogs without some
Xexplicit request by the user. The time to hit a target which moves
Xaround arbitrarily will always be T(1)!
X.PP
XIn many cases, the Power Law will also work for sequences of
Xoperations to even greater effect. If you are a touch typist, you
Xcan observe this effect by comparing how fast you can enter "the"
Xin comparison to three random letters. We'll come back shortly
Xto consider what we can do to encourage this phenomenon.
X.SH EYES
XJust as fingers are the way the user sends data to the
Xcomputer, so the eyes are his channel from the machine. The rate
Xat which information may be passed to the user is determined by
Xthe "cycle time" of his visual processor. Experimental results
Xshow that this time ranges between 50 and 200 milliseconds.
X.PP
XEvents separated by 50 milliseconds or less are always
Xperceived as a single event. Those separated by more than 200
Xmilliseconds are always seen as separate. We can use these
Xfacts in optimizing user of the computer's power when driving the
Xinterface.
X.PP
XSuppose your application's interface contains an icon which
Xshould be inverted when the mouse passes over it. We now know
Xthat flipping it within one twentieth of a second is necessary
Xand sufficient. Therefore, if a "first cut" at the program achieves
Xthis performance, there is no need for further optimization, unless
Xyou want to interleave other operations. If it falls short, it will
Xbe necessary to do some assembly coding to achieve a smooth feel.
X.PP
XOn the other hand, two actions which you want to appear distinct
Xor convey two different pieces of information must be separated
Xby an absolute minimum of a fifth of a second, even assuming that
Xthey occur in an identical location on which the user's attention
Xis already focused.
X.PP
XWe are able to influence the visual processing rate within the
X50 to 200 millisecond range by changing the intensity of the stimulus
Xpresented. This can be done with color, by flashing a target, or
Xby more subtle enhancements such as bold face type. For instance,
Xmost people using GEM soon become accustomed to the "paper white"

Xbackground of most windows and dialogs. A dialog which uses a
Xreverse color scheme, white letters on black, is visually shocking
Xin its starkness, and will immediately draw the user's eyes.
X.PP
XIt should be quickly added that stimulus enhancement will only
Xwork when it unambiguously draws attention to the target. Three or
Xfour blinking objects scattered around the screen are confusing, and
Xworse than no enhancement at all!
X.SH SHORT-TERM MEMORY
XBoth the information gathered by the eyes
Xand movement commands on their way to the hand pass through short-term
Xmemory (also called working memory). The amount of information which
Xcan be held in short-term memory at any one time is limited. You can
Xdemonstrate this limit on yourself by attempting to type a sheet of
Xrandom numbers by looking back and forth from the numbers to the
Xscreen. If you are like most people, you will be able to remember
Xbetween five and nine numbers at a time. So universal is this
Xfinding that it is sometimes called "the magic number seven, plus
Xor minus two".
X.PP
XThis short-term capacity sets a limit on the number of choices
Xwhich the user can be expected to grasp at once. It suggests that
Xthe number of independent choices in a menu, for instance, should
Xbe around seven, and never exceed nine. If this limit is violated,
Xthen the user will have to take several glances, with pauses to
Xthink, in order to make a choice.
X.SH CHUNKING
XThe effective capacity of short-term memory can be
Xincreased when several related items are mentally grouped as a "chunk".
XHumans automatically adopt this strategy to save themselves time.
XFor instance, random numbers had to be used instead of text in the
Xexample above, because people do not type their native language as
Xindividual characters. Instead, they combine the letters into words
Xand remember these chunks instead. Put another way, the characters
Xare no longer considered as individual choices.
X.PP
XA well designed interface should promote the use of chunking
Xas a strategy by the user. One easy way is to gather together
Xrelated options in a single place. This is one reason that like
Xcommands are grouped into a single menu which is hidden except for
Xits title. If all of the menu options were "in the open", the user
Xwould be overwhelmed with dozens of alternatives at once. Instead, a
X"Show Info" command, for instance, becomes two chunks: pick File
Xmenu, then pick Show.
X.PP
XSometimes the interface can accomplish the chunking for the user.
XConsider the difference between a slider bar in a GEM program, and
Xa three digit entry field in a text mode application. Obviously,
Xthe GEM user has fewer decisions to make in order to set the associated
Xvariable.
X.SH THINK!
XWhile we are puttering around trying to speed up
Xthe keyboard, the mouse, and the screen, the user is actually

Xtrying to get some work done. We need to back off now, and
Xlook at the ways of thinking, or cognitive processes, that go into
Xaccomplishing the job.
X.PP
XThe user's goal may be to enter and edit a letter, to retrieve
Xinformation from a database, or simply draw a picture, but it
Xprobably has very little to do with programming. In fact, the
XProblem Space Principle says that the task can be described as
Xa set of states of knowledge, a set of operators and associated
Xconstraints for changing the states, and the knowledge to
Xchoose the appropriate operator, which resides in the user's head.
X.PP
XThose with a background in systems theory can consider this
Xas a somewhat abstract, but straightforward, statement in terms of
Xstate variables and operators. A programmer might compare the
Xknowledge states to the values of variables, the operators to
Xarithmetic and logic operations, the constraints to the rules of
Xsyntax, and the user's knowledge to the algorithm embodied by a
Xprogram.
X.SH ARE WE NOT MEN?
XA rational person will try to attain his
Xgoals (get the job done) by changing the state of his problem space
Xfrom its initial state to the goal state. The initial state,
Xfor instance, might be a blank word processor screen. The desired
Xfinal state is to have a completed business letter on the screen.
X.PP
XThe Rationality Principle says that the user's behavior in
Xtyping, mousing, and so on, can be explained by considering the
Xtasks required to achieve the goal, the operators available to
Xcarry out the tasks, and the limitations on the user's knowledge,
Xobservations, and processing capacity. This sounds like the
Xtypical user of a computer program must spend a good deal of time
Xscratching his head and wondering what to do next. In fact, one
Xof Card and Moran's key results is that this is NOT what takes place.
X.PP
XWhat happens, in fact, is that the trained user strikes a sort
Xof "modus vivendi" with his tool and adopts a set of repetitive,
Xtrained behavior patterns as the best way to get the job done.
XHe may go so far as to ignore some functions of the program in
Xorder to set up a reliable pattern. What we are looking for is a
Xway of measuring and predicting the "quality" of this trained
Xbehavior. Since using computers is a human endeavor, we should
Xconsider not only the speed with which the task is completed, but
Xthe degree of annoyance or pleasure associated with the process.
X.PP
XCard and Moran constructed a series of behavioral models which
Xthey called GOMS models, for Goals-Operators-Methods-Selection.
XThese models suggested that in the training process the user
Xlearned to combine the basic operators in sequences (chunks!)
Xwhich then became methods for reaching the goals. Then these
Xfirst level methods might be combined again into second level
Xmethods, and so forth, as the learning progressed.
X.PP

XThe GOMS models were tested in a lengthy series of trials
Xat Xerox PARC using a variety of word processing software. (Among
Xthe subjects of these experiments were the inventors of
Xthe windowing methods used in GEM!) The results were again
Xsurprising: the level of detail in the models was really unimportant!
X.PP
XIt turned out to be sufficient to merely count up the number
Xof keystrokes, mouse movements, and thought intervals required
Xby each task. After summing up all of the tasks, any extra time
Xfor the computer to respond, or the user to move his hands from
Xkeyboard to mouse, or eyes from screen to printed page is added in.
XThis simplified version is called the Keystroke-Level Model.
X.PP
XAs an example of the Keystroke Model, consider the task of
Xchanging a mistyped letter on the screen of a GEM word processor.
XThis might be broken down as follows: 1) find the letter on the screen;
X2) move hand to mouse; 3) point to letter; 4) click mouse button;
X5) move hand to keyboard; 6) strike "Delete" key; 7) strike key
Xfor new character.
X.PP
XThe sufficiency of the Keystroke Model is great news for our
Xattempt to design faster interfaces. It says we can concentrate
Xour efforts on minimizing the number of total actions to be taken,
Xand making sure that each action is as fast as possible. We have
Xalready discussed some ways to speed up the mouse and keyboard
Xactions, so let's now consider how to speed up the thought intervals,
Xand cut the number of actions.
X.PP
XOne way to cut down "think time" is to make sure that the
Xcapacity of short-term memory is not exceeded during the course of
Xa task. For example, the fix-a-letter task described above required
Xthe user to remember 1) his place in the overall job of typing the
Xdocument; 2) the task he is about to perform; 3) where the bad
Xcharacter appeared, and 4) what the new character was. When this
Xtotal of items creeps toward seven, the user often loses his place
Xand commits errors.
X.PP
XYou can appreciate the ubiquity of this problem by considering
Xhow many times you have made mistakes nesting parentheses,
Xor had to go back to count them, because too many things happened
Xwhile typing the line to remember the nesting levels. The moral is that
Xoperations with long strings of operands should be avoided when
Xdesigning an interface.
X.PP
XThe single most important factor in making an interface
Xcomfortable to use is increasing its predictability, and
Xdecreasing the amount of indecision present at each step during
Xa task. There is (inevitably) an Uncertainty Principle which
Xrelates the number of choices at each step to the associated
Xtime for thought:
X.sp 1
X.ce 1
XT = I * LOG2 (N + 1)

X.sp 1
Xwhere LOG2 is the binary logarithm function, N is the number of
Xequally probable choices, and I is a constant of approximately
X140 msec/bit. When the alternates are not equally probable, the
Xfunction is more complex:
X.sp 1
X.ce 1
XT = I * SUM-FOR-i-FROM-1-TO-N (P(i) * LOG2(1 / P(i) + 1))
X.sp 1
Xwhere the P(i) are the probabilities of each of the choices (which
Xmust sum to one). (SUM-FOR-i... is the best I can do for a sigma
Xoperator on-line!) Those of you with some information theory
Xbackground will recognize this formula as the entropy of
Xthe decision; we'll come back to that later.
X.PP
XSo what can we learn from this hash? It turns out, as we might
Xexpect, that we can decrease the decision time by making some
Xof the user's choices more probable than others. We do that by
Xmeans of feedback cues from the interface.
X.PP
XThe important of reliable, continuous meaningful feedback
Xcannot be emphasized enough. It helps the beginner learn the system,
Xand its predictability makes the program comfortable for the expert.
XPrograms with no feedback, or unreliable cues, produce confusion,
Xdissonance, and frustration in the user.
X.PP
XThis principle is so important that I going to give several
Xexamples from common GEM practice. The Desktop provides several
Xinstances. When an object is selected and a menu drops down, only
Xthose choices which are legal for the object are in black. The
Xothers are dimmed to grey, and are therefore removed from the
Xdecision. When a pick is made from the menu, the bar entry remains
Xblack until the operation is complete, reassuring the user that
Xthe correct choice was made. In both the Desktop and the RCS,
Xitems which are double-clicked open up with a "zoom box" from
Xthe object, again showing that the right object was picked.
X.PP
XOther techniques are useful when operator icons are exposed on
Xthe screen. When an object is picked, the legal operations might
Xbe outlined, or the bad choices might be dimmed. If the screen
Xflashing produced by this is objectionable, the legal icons can
Xbe made mouse sensitive, so they will "light up" when the cursor
Xpasses over - again showing the user which choices are legal.
X.PP
XThe desire for feedback is so strong that it should be provided
Xeven while the computer is doing an operation on its own. The hour
Xglass mouse form is a primitive example of this. More sophisticated
Xare "progress indicators" such as animated thermometer bars,
Xclocks, or text displays of the processing steps. The ST Desktop
Xprovides examples in the Format and Disk Copy functions. The purpose
Xof all of these is to reassure the user that the operation is
Xprogressing normally. Their lack can lead to amusing spectacles
Xsuch as secretaries leaning over to hear if their disk drives are

Xworking!
X.PP
XAnother commonly overlooked feature is error prevention and
Xcorrection. Card and Moran's results showed that in order to go
Xfaster, people will tolerate error rates of up to 30% in their
Xwork. Any program which does not give a fast way to fix mistakes
Xwill be frustrating indeed!
X.PP
XThe best way to cope with an error is to "make it didn't happen",
Xto quote a common child's phrase. The same feedback methods
Xdiscussed above are also effective in preventing the user from
Xpicking inappropriate combinations of objects and operations.
XReplacement of numeric type-ins with sliders or other visual
Xcontrols eliminates the common "Range Error". The use of radio
Xbuttons prevents the user from picking incompatible options.
XWhen such techniques are used consistently, the beginner also
Xgains confidence that he may explore the program without blundering
Xinto errors.
X.PP
XOnce an error has occured, the best solution is to have an
X"inverse operation" immediately available. For instance, the way
Xto fix a bad character is to hit the backspace key. If a line is
Xinadvertantly deleted, there should be a way to restore it.
X.PP
XSometimes the mechanics of providing true inverses are
Ximpractical, or end up cluttering the interface themselves. In
Xthese cases, a global "Undo" command should be provided to
Xreverse the effect of the last operation, no matter what it was.
X.SH OF MODES AND BANDWIDTH
XNow I am going to depart from
Xthe Card, Newell and Moran thread of discussion to consider
Xhow we can minimize the number of operations in a task by
Xaltering the modes of the interface. Although "no modes" has
Xbeen a watchword of Macintosh developers, the term may need
Xdefinition for Atarians.
X.PP
XSimply stated, a mode exists any time you cannot get to
Xall of the capabilities of the program without taking some
Xintermediate step. Familiar examples are old-style "menu-driven"
Xprograms, in which user must make selections from a number of
Xnested menus in order to perform any operation. The options
Xof any one menu are unavailable from the others.
X.PP
XRecall that the user is trying to accomplish work in his
Xown problem space, by altering its states. A mode in the
Xprogram adds additional states to the problem space, which he is
Xforced to consider in order to get the job done. We might call
Xan interface which is completely modeless "transparent", because it
Xadds no states between the user and his work. One of the best
Xexamples of a transparent program is the 15-puzzle in the Macintosh
Xdesk accessory set. The problem space of rearranging the tiles
Xis identical between the program and a physical puzzle.
X.PP

XUnfortunately, most programmers find themselves forced to
Xput modes of some sort into their programs. These often arise
Xdue to technological limitations, such as memory space, screen
X"real estate", or performance limitations of peripherals. The
Xquestion is how the modes can be made least offensive.
X.PP
XI will make the general claim that the frustration which a
Xmode produces is directly proportional to the amount of the user's
Xbandwidth which it consumes. In other words, we need to consider
Xhow many keystrokes, mouse clicks, eye movements, and so on, are
Xgoing into manipulating the true problem states, and how many
Xare being absorbed by the modes of the program. If the interface
Xis wasting a large amount of the user's effort, it will be perceived
Xas slow and annoying.
X.PP
XHere we can consider again the hierarchy of goals and methods
Xwhich the user employs. When the mode is low in the hierarchy,
Xand close to the user's "fingertips", it is encountered the most
Xfrequently. For instance, consider how frustrating it would be
Xto have to hit a function key before typing in each character!
X.PP
XThe "menu-driven" style of programs mentioned above are
Xalmost as bad, since usually only one piece of information is
Xcollected at each menu. Such a program becomes a labyrinth of
Xstates better suited to an adventure game!
X.PP
XThe least offensive modes are found at the higher, goal
Xrelated levels of the hierarchy. The better they align with
Xchanges in the state of the original problem, the more they
Xare tolerated. For example, a word processing program might
Xhave one screen layout for program editing, another for writing
Xletters, and yet another while printing the documents. A
Xmulti-function business package might have one set of menus for
Xthe spreadsheet, another for a graphing module, and a third
Xfor a database.
X.PP
XIn some cases the problem solved by the program has convenient
X"fracture lines" which can be used to define the modes. An
Xexample in my own past is the RCS, where the editing of each
Xtype of resource tree forms its own mode, with each of the modes
Xnested within the overall mode and problem of composing the
Xentire resource tree.
X.SH TO DO IS TO BE!
XAny narrative description of user interface
Xis bound to be lacking. There is no way text can convey the vibrancy
Xand tactile pleasure of a good interface, or the sullen boredom
Xof a bad one. Therefore, I encourage you to experiment. Get out
Xyour favorite arcade game and see if you can spot some of the
Xelements I have described. Dig into your slush pile for the most
Xannoying program you have ever seen, run it and see if you can see
Xmistakes. How would you fix them? Then... go do it to your own
Xprogram!
X.SH AMEN...

```
XThis concludes the sermon.  I'd like some Feedback
Xas to whether you found this Boring Beyond Belief or Really Hot
XStuff.  If enough people are interested, homily number two will
Xappear a few episodes from now.   The very next installment of ST
XPRO GEM will go back to basics to explore VDI drawing primitives.
XIn the meantime, you might investigate some of the Good Books on
Xinterface design referenced below.

X.PART IX VDI Graphics: Lines and Solids
X.PP
XThis  issue  of ST PRO GEM is the first in a  series  of  two
Xwhich  will explore the fundamentals of VDI graphics  output.   In
Xthis installment, we will take a look at the commands necessary to
Xoutput simple graphics such as lines,  squares and circles as well
Xas  more complex figures such as polygons.   The following episode
Xwill  take a first look at graphics text output,  with an emphasis
Xon  ways  to  optimize its drawing speed.   It will  also  include
Xanother  installment  of ONLINE Feedback.   As usual,  there is  a
Xdownload  with  this column.   You should find it under  the  name
XGEMCL9.C in DL3 of ATARI16 (PCS-58).
X.SH A  BIT  OF HISTORY
XOne  of  the reasons that the VDI can  be  confusing  is  that
Xdrawing anything at all,  even a simple line,  can involve setting
Xaround four different VDI parameters before making the draw  call!
X(Given  the state of the GEM documents,  just FINDING them can  be
```

Xfun!) Looking backwards a bit sheds some light on why the VDI is
Xstructured this way, and also gives us a framework for organizing
Xa discussion of graphics output.
X.PP
XThe GEM VDI closely follows the so-called GKS standard, which
Xdefines capabilities and calling sequences for a standardized
Xgraphic input/output system.   GKS is itself an evolution from an
Xearly system called "Core".   Both of these standards were born in
Xthe days when pen plotters, vectored graphics displays, and
Xminicomputers were the latest items.   So, if you wonder why
Xsetting the drawing pen color is a separate command, just think
Xback a few years when it actually meant what it says!   (The
Xcynical   may   choose   instead   to   ponder   the   benefits   of
Xstandardization.)
X.PP
XWhen doing VDI output, it helps if you pretend that the
Xdisplay screen really is a plotter or some other separate device,
Xwhich has its own internal parameters which you can set up and
Xread back.   The class of VDI commands called Attribute Functions
Xlet you set the parameters.   Output Functions cause the "device"
Xto actually draw someone once it is configured.   The Inquire
XFunctions let you read back the parameters if necessary.
X.PP
XThere are two parameters which are relevant no matter what
Xtype of object you are trying to draw.   They are the writing mode
Xand the clipping rectangle.   The writing mode is similar to that
Xdiscussed in the column on raster operations.   It determines what
Xeffect the figure you are drawing will have on data already on the
Xscreen. The writing mode is set with the call:
X.FB vswr_mode()
Xvswr_mode(vdi_handle, mode);
X.FE
XVdi_handle, here and below, is the handle obtained from
Xgraf_handle at the beginning of the program. Mode is a word which
Xmay be one of:
X.sp 1
X.in +8
X1 - Replace Mode
X.br
X2 - Transparent Mode
X.br
X3 - XOR mode
X.br
X4 - Reverse Transparent Mode
X.in -8
X.PP
XIn replace mode, whatever is on the screen is overwritten.
XIf you are writing characters, this means the background of each
Xcharacter cell will be erased.
X.PP
XIn transparent mode, only the pixels directly under the
X"positive" part of the image, that is, where 1-bits are being
Xwritten, will be changed. When writing characters, the background

Xof the cell will be left intact.
X.PP
XIn XOR mode, an exclusive or is performed between the screen Xcontents and what is being written. The effect is to reverse the Ximage under areas where a 1-bit occurs.
X.PP
XReverse transparent is like transparent, but with a "reverse Xcolor scheme". That is, only places where a 0-bit is to be Xput are changed to the current writing color. When you Xwrite characters in reverse transparent (over white), the effect Xis reverse video.
X.PP
XThe other common parameter is the clipping rectangle. It Xdefines the area on the screen where the VDI is permitted to draw. XAny output which would fall outside of this area is ignored; it is Xeffectively a null operation. The clip rectangle is set with the Xcall:
X.FB vs_clip()
Xvs_clip(vdi_handle, flag, pxy);
X.FE
XPxy is a four-word array. Pxy[0] and pxy[1] are the X and Y Xscreen coordinates, respectively, of one corner of your clipping Xrectangle. Pxy[2] and pxy[3] are the coordinates of the Xdiagonally opposite corner of the rectangle. (When working with Xthe AES, use of a GRECT to define the clip is often more Xconvenient. The routine set_clip() in the download does this.)
X.PP
XFlag is set to TRUE if clipping is to be used. If you set it Xto FALSE, the entire screen is assumed to be fair game.
X.PP
XNormally, you should walk the rectangle list for the current Xwindow to obtain your clipping rectangles. (See ST PRO GEM #2 for Xmore details.) However, turning off the clip speeds up all output Xoperations, particularly text. You may do this ONLY when you are Xabsolutely certain that the figure you are drawing will not extend Xout of the top-most window, or out of a dialog.
X.SH THE LINE FORMS ON THE LEFT
XThe VDI line drawing operations include polyline, arc, Xelliptical arc, and rounded rectangle. I'll first look at the XAttribute Functions for line drawing, then go through the drawing Xprimitives themselves.
X.PP
XThe most common used line attributes are color and width. XThe color is set with:
X.FB vsl_color()
Xvsl_color(vdi_handle, color);
X.FE
Xwhere color is one of the standard VDI color indices, ranging Xfrom zero to 15. (As discussed in column #6, the color which Xactually appears will depend on the pallette setting of your ST.)
X.PP
XThe line width may only be set to ODD positive values, for Xreasons of symmetry. If you try to set an even value, the VDI

Xwill take the next lower odd value. The call is:
X.FB vsl_width()
Xvsl_width(vdi_handle, width);
X.FE
XThe two less used line parameters are the end style and
Xpattern. With the end style you can cause the output line to
Xhave rounded ends or arrowhead ends. The call is:
X.FB vsl_ends()
Xvsl_ends(vdi_handle, begin_style, end_style);
X.FE
XBegin_style and end_style are each words which may have the
Xvalues zero for square ends (the default), one for arrowed ends,
Xor two for rounded ends. They determine the styles for the
Xstarting and finishing ends of the line, respectively.
X.PP
XThe line pattern attribute can select dotted or dashed lines
Xas well as more complicated patterns. Before continuing, you
Xshould note one warning: VDI line output DOES NOT compensate for
Xpixel aspect ratio. That is, the dashes on a line will look twice
Xas long drawn vertically on a medium-res ST screen as they do when
Xdrawn horizontally. The command for setting the pattern is:
X.FB vsl_type()
Xvsl_type(vdi_handle, style);
X.FE
XStyle is a word with a value between 1 and 7. The styles
Xselected are:
X.sp 1
X.in +8
X1 - Solid (the default)
X.br
X2 - Long Dash
X.br
X3 - Dot
X.br
X4 - Dash, Dot
X.br
X5 - Dash
X.br
X6 - Dash, Dot, Dot
X.br
X7 - (User defined style)
X.in -8
X.PP
XThe user defined style is determined by a 16-bit pattern
Xsupplied by the application. A one bit in the pattern turns a
Xpixel on, a zero bit leaves it off. The pattern is cycled through
Xrepeatedly, using the high bit first. To use a custom style, you
Xmust make the call:
X.FB vsl_udsty()
Xvsl_udsty(vdi_handle, pattern);
X.FE
Xbefore doing vsl_type().
X.PP

XAs I mentioned above, the line type Output Functions
Xavailable are polyline, circular and ellliptical arc, and rounded
Xrectangle. Each has its own calling sequence. The call for a
Xpolyline is:
X.FB v_pline()
Xv_pline(vdi_handle, points, pxy);
X.FE
XPoints tells how many vertices will appear on the polyline. For
Xinstance, a straight line has two vertices: the end and the
Xbeginning. A closed square would have five, with the first and
Xlast identical. (There is no requirement that the figure
Xdescribed be closed.)
X.PP
XThe pxy array contains the X and Y raster coordinates for the
Xvertices, with a total of 2 * points entries. Pxy[0] and pxy[1]
Xare the first X-Y pair, and so on.
X.PP
XIf you happen to be using the XOR drawing mode, remember that
Xdrawing twice at a point is equivalent to no drawing at all.
XTherefore, for a figure to appear closed in XOR mode, the final
Xstroke should actually stop one pixel short of the origin of the
Xfigure.
X.PP
XYou may notice that in the GEM VDI manual the rounded
Xrectangle and arc commands are referred to as GDPs (Generalized
XDrawing Primitives). This denotation is historical in nature, and
Xhas no effect unless you are writing your own VDI bindings.
X.PP
XThe rounded rectangle is nice to use for customized buttons
Xin windows and dialogs. It gives a "softer" look to the screen
Xthan the standard square objects. The drawing command is:
X.FB v_rbox()
Xv_rbox(vdi_handle, pxy);
X.FE
XPxy is a four word array giving opposite corners of the
Xrectangle, just as for the vs_clip() call. The corner rounding
Xoccurs within the confines of this rectangle. Nothing will
Xprotrude unless you specify a line thickness greater than one.
XThe corner rounding is approximately circular; there is no user
Xcontrol over the degree or shape of rounding.
X.PP
XBoth the arc and elliptical arc commands use a curious method
Xof specifying angles. The units are tenths of degrees, so an
Xentire circle is 3600 units. The count starts at ninety degrees
Xright of vertical, and proceeds counterclockwise. This means that
X"3 o'clock" is 0 units, "noon" is 900 units, "9 o'clock" is 1800
Xunits, and 2700 units is at "half-past". 3600 units take you back
Xto "3 o'clock".
X.PP
XThe command for drawing a circular arc is:
X.FB v_arc()
Xv_arc(vdi_handle, x, y, radius, begin, end);
X.FE

XX and y specify the raster coordinates of the center of the
Xcircle. Radius specifies the distance from center to all points
Xon the arc. Begin and end are angles given in units as described
Xabove, both with values between 0 and 3600. The drawing of the
Xarc ALWAYS proceeds counterclockwise, in the direction of
Xincreasing arc number. So values of 0 and 900 for begin and end
Xwould draw a quarter circle from "three o'clock" to "noon".
XReversing the values would draw the other three quarters of the
Xcircle.
X.PP
XA v_arc() command which specifies a "full turn" is the
Xfastest way to draw a complete circle on the screen. Be warned,
Xhowever, that the circle drawing algorithm used in the VDI seems
Xto have some serious shortcomings at small radii! You can
Xexperiment with the CIRCLE primitive in ST Logo, which uses
Xv_arc(), to see what I mean.
X.PP
XNotice that if you want an arc to strike one or more given
Xpoints on the screen, then you are in for some trigonometry. If
Xyour math is a bit rusty, I highly recommend the book "A
XProgrammer's Geometry", by Bowyer and Woodwark, published by
XButterworths (London, Boston, Toronto).
X.PP
XFinally, the elliptical arc is generated with:
X.FB v_ellarc()
Xv_ellarc(vdi_handle, x, y, xrad, yrad, begin, end);
X.FE
XX, y, begin, and end are just as before. Xrad and yrad give the
Xhorizontal and vertical radii of the defining ellipse. This means
Xthat the distance of the arc from center will be yrad pixels at
X"noon" and "half-past", and it will be xrad pixels at "3 and 9
Xo'clock". Again, the arc is always drawn counterclockwise.
X.PP
XThere are a number of approaches to keeping the VDI's
Xattributes "in sync" with the actual output operations. Probably
Xthe LEAST efficient is to use the Inquire Functions to determine
Xthe current attributes. For this reason, I have omitted a
Xdiscussion of these calls from this column.
X.PP
XAnother idea is to keep a local copy of all significant
Xattributes, use a test-before-set method to minimize the number of
XAttribute Functions which need to be called. This puts a burden
Xon the programmer to be sure that the local attribute variables
Xare correctly maintained. Failure to do so may result in obscure
Xdrawing bugs. If your application employs user defined AES
Xobjects, you must be very careful because GEM might call your draw
Xcode in the middle of a VDI operation (particularly if the user
Xdefined objects are in the menu).
X.PP
XAlways setting the attributes is a simplistic method, but
Xoften proves most effective. The routines pl_perim() and
Xrr_perim() in the download exhibit this approach. Modification
Xfor other primitives is straightforward. This style is most

Xuseful when drawing operations are scattered throughout the Xprogram, so that keeping track of the current attribute status is Xdifficult. Although inherently inefficient, the difference is not Xvery noticable if the drawing operation requested is itself time Xconsuming.
X.PP
XIn many applications, such as data graphing programs or X"Draw" packages, the output operations are centralized, forming Xthe primary functionality of the code. In this case, it is both Xeasy and efficient to keep track of attribute status between Xsuccessive drawing operations.
X.SH SOLIDS
XThere are a wider variety of VDI calls for drawing solid Xfigures. They include rectangle or bar, disk, pie, ellipse, Xelliptical pie, filled rounded rectangle, and filled polygonal Xarea. Of course, filled figure calls also have their own set of Xattributes which you will need to set.
X.PP
XThe fill color index determines what pen color will be used Xto draw the solid. It is set with:
X.FB vsf_color()
Xvsf_color(vdi_handle, color);
X.FE
XColor is just the same as for line drawing. A solid may or Xmay not have a visible border. This is determined with the call:
X.FB vsf_perimeter()
Xvsf_perimeter(vdi_handle, vis);
X.FE
XVis is a Boolean. If it is true, the figure will be given a Xsolid one pixel outline in the current fill color index. This is Xoften useful to improve the appearance of solids drawn with a Xdithered fill pattern. If vis is false, then no outline is drawn.
X.PP
XThere are two parameters which together determine the pattern Xused to fill your figure. They are called interior style and Xinterior index. The style determines the general type of fill, Xand the index is used to select a particular pattern if necessary. XThe style is set with the command:
X.FB vsf_interior()
Xvsf_interior(vdi_handle, style);
X.FE
Xwhere style is a value from zero through four. Zero selects a Xhollow style: the fill is performed in color zero, which is Xusually white. Style one selects a solid fill with the current Xfill color. A style of two is called "pattern" and a three is Xcalled "hatch", which are terms somewhat suggestive of the options Xwhich can then be selected using the interior index. Style four Xselects the user defined pattern, which is described below.
X.PP
XThe interior index is only significant for styles two and Xthree. To set it, use:
X.FB vsf_style()
Xvsf_style(vdi_handle, index);

X.FE
X(Be careful here: it is very easy to confuse this call with the
Xone above due to the unfortunate choice of name.) The index
Xselects the actual drawing pattern. The GEM VDI manual shows fill
Xpatterns corresponding to index values from 1 to 24 under style 2,
Xand from 1 to 12 under style 3. However, some of these are
Ximplemented differently on the ST. Rather than try to describe
Xthem all here, I would suggest that you experiment. You can do so
Xeasily in ST Logo by opening the Graphics Settings dialog and
Xplaying with the style and index values there.
X.PP
XThe user defined style gives you some interesting options for
Xmulti-color fills. It is set with:
X.FB vsf_udpat()
Xvsf_udpat(vdi_handle, pattern, planes);
X.FE
XPlanes determines the number of color planes in the pattern
Xwhich you supply. It is set to one if you are setting a
Xmonochrome pattern. (Remember, monochrome is not necessarily
Xblack). It may be set to higher values on color systems: two for
XST medium-res mode, or four for low-res mode. If you use a number
Xlower than four under low-res, the other planes are zero filled.
X.PP
XThe pattern parameter is an array of words which is a
Xmultiple of 16 words long. The pattern determined is 16 by 16
Xpixels, with each word forming one row of the pattern. The rows
Xare arranged top to bottom, with the most significant bit to the
Xleft. If you have selected a multi-plane pattern, the entire
Xfirst plane is stored, then the second, and so on.
X.PP
XNote that to use a multi-plane pattern, you set the writing
Xmode to replace using vswr_mode(). Since the each plane can be
Xdifferent, you can produce multi-colored patterns. If you use a
Xwriting color other than black, some of the planes may
X"disappear".
X.PP
XMost of the solids Output Functions have analogous line
Xdrawing commands. The polyline command corresponds to the filled
Xarea primitive. The filled area routine is:
X.FB v_fillarea()
Xv_fillarea(vdi_handle, count, pxy);
X.FE
XCount and pxy are just the same as for v_pline(). If the
Xpolygon defined by pxy is not closed, then the VDI will force
Xclosure with a straight line from the last to the first point.
XThe polygon may be concave or self-intersecting. If perimeter
Xshow is on, the area will be outlined.
X.PP
XOne note of caution is necessary for both v_fillarea() and
Xv_pline(). There is a limit on the number of points which may be
Xstored in pxy[]. This limit occurs because the contents of pxy[]
Xare copied to the intin[] binding array before the VDI is called.
XYou can determine the maximum number of vertices by checking

Xintout[14] after using the extended inquire function vq_extnd().
X.PP
XFor reasons unknown to this writer, there are TWO different
Xfilled rectangle commands in the VDI. The first is
X.FB vr_recfl()
Xvr_recfl(vdi_handle, pxy);
X.FE
XPxy is a four word array defining two opposite corners of the
Xrectangle, just as in vs_clip(). Vr_recfl() uses the fill
Xattribute settings, except that it NEVER draws a perimeter.
X.PP
XThe other rectangle routine is v_bar(), with exactly the same
Xarguments as vr_recfl(). The only difference is that the
Xperimeter setting IS respected. These two routines are the
Xfastest way to produce a solid rectangle using the VDI. They may
Xbe used in XOR mode with a BLACK fill color to quickly invert an
Xarea of the screen. You can improve the speed even further by
Xturning off the clip (if possible), and byte aligning the left and
Xright edges of the rectangle.
X.PP
XSeparate commands are provided for solid circle and ellipse.
XThe circle call is:
X.FB v_circle()
Xv_circle(vdi_handle, x, y, radius);
X.FE
Xand the ellipse command is:
X.FB v_ellipse()
Xv_ellipse(vdi_handle, x, y, xrad, yrad);
X.FE
XAll of the parameters are identical to those given above for
Xv_arc() and v_ellarc(). The solid analogue of an arc is a "pie
Xslice". The VDI pie commands are:
X.FB v_pieslice()
Xv_pieslice(vdi_handle, x, y, radius, begin, end);
X.FE
Xfor a slice from a circular pie, and
X.FB v_ellpie()
Xv_ellpie(vdi_handle, x, y, xrad, yrad, begin, end);
X.FE
Xfor a slice from a "squashed" pie. Again, the parameters are
Xidentical to those in v_arc() and v_ellarc(). The units and
Xdrawing order of angles are also the same. The final solids
XOutput Function is:
X.FB v_rfbox()
Xv_rfbox(vdi_handle, pxy);
X.FE
Xwhich draws a filled rounded rectangle. The pxy array defines
Xtwo two opposite corners of the bounding box, as shown for
Xvs_clip().
X.PP
XThe issues involved in correctly setting the VDI attributes
Xfor a fill operation are identical to those in drawing lines. For
Xthose who want to employ the "always set" method, I have again

```
Xincluded  two  skeleton  routines in the download,  which  can  be
Xmodified as desired.
X.SH TO  BE  CONTINUED
XThis concludes the first part of our expedition  through  basic
XVDI  operations.   The  next  issue will tackle  the  problems  of
Xdrawing  bit mapped text at a reasonable speed.   This first  pass
Xwill  not attempt to tackle alternate or  proportional  fonts,  or
Xalternate font sizes.   Instead,  I will concentrate on techniques
Xfor  squeezing greater performance out of the standard  monospaced
Xsystem fonts.

Lines: 20

I was over at a friends house who just got the MEGAMAX "C"
compiler for his 520ST. There seems to be a bug with the
printf function. For example:

```
#include <stdio.h>
main()
{
     int c;

     printf("Hello world\n");
     printf("Enter a Char:");
     c = getchar();
}
```

Does not Work until you put a "\n" in the second
printf statement.

ihnet!bryan
p.s. We tried calling the program a.tos, but that did not help either

A friend of mine is interested in getting computer assistance with writing music
for the guitar. Does anybody have experience with any packages which might be
suitable for this application? What he needs is a "music word processor" that can
write the
sheet music as well as playing the music. Singing it would I think be
unnecessary.

Any help that is available will be appreciated. Thanks!

Am I missing something here? I tried to use stusq.ttp on the pdforth that
was posted to the net a while ago and couldn't get the unsqueezer to work.
I put everything on disk A, clicked on stusq.ttp, entered pdforth.tqs, and
hit return. The disk was accessed for about half a second and the program
came back with nothing. I looked at the uudecoded version and found a bunch
of ^@ at the very beginning. This doesn't seem normal to me. Below is the
first few lines of the uuencoded version of stusq.ttp. Can someone tell me
if this is right and what I am doing wrong? (by the way, I haven't had
any trouble uudecodeing on UNIX and down loading to my 520st, before this)

```
begin 644 stusq.ttp

Since noone has answered my question yet, here it is for anyone who's
interested (the question was how do the new ST's generate 60Hz and 70Hz
video simultaneously):

In fact they don't. The 70Hz monitor, if used, is detected and causes the
ST to generate the appropriate video signals. Otherwise 60 Hz (only) is
generated, at least I think this is what happens.

I too am a 1st Word fan and have experienced the same problems you have,
but like you don't consider them major problems.

I have come up with a major problem though. I haven't printed out a
copy of the guide.doc that comes with 1st Word since I just load it
and read it on the screen if there is something I can't figure out
without it. Well, last week I loaded the guide and found
the file I was editing right in the middle out it. I hadn't done any disk
swapping (which seems to wreak havoc with TOS) or anything else funny.
Somehow, the file (prolog.doc) just got saved in the middle. So I put
 a fresh copy of the guide on the work disk and went on working on prolog.doc.
The next time I looked at guide.doc, the same thing happened again.

Fortunately, only the Guide (that is backed up) was crashed, but this is
a cause for worry since I don't know when it might occur. Also, I wonder if
it is a bug in TOS (considering my past experiences with swapping disks and
having the old disk's directory written on the new disk). Has TOS in ROM
solved this problem?

Another thing, how do you get 1st Word to double space?

These questions are for Atari or anyone who may know something about them.

1) What exactly is Gdos?

2) It is supposedly available to developers now. Is it?

3) There is apparently a fix to ar68 that is rumored to make the size of the object files even. Is there a fix? What does it fix?

4) Once you put a reasonable number of files on the harddisk it gets ungodly slow when trying to open a file for write/create. Reading files is still fine. Why is this so ? (I use the new AHDI that is making the rounds nowadays).

5) The documentation for DUP and FORCE ($45 and $46 in Gemdos) in the HH guide is very vague. Could you clarify the difference between them?

As they say, thanks in advance.

I'm interested in the status of Kermit on the Atari ST. Do you folks
have any idea of where it's available, who's working on it, or
where it might be archived? Ditto any commericial communications
programs that have it implemented.

I was only able to get this (and any other *.ACC stuff) to work after
naming the program DESKn.ACC (DESK1.ACC, DESK2.ACC, etc.).

I have ceased transmitting binaries due to several complaints and the
fact that several others were unable to get them off the net intact.

Judging from the mail I have received, I would say there is great interest
in the wide distribution of PD software. Much of this is apparently due
to the many students who own STs and our European friends that do not have
access to the vast quantities of PD stuff available here in the states.
However, many people in other categories are interested in this software
perhaps because there still is relatively little software for sale.

Because of the great interest and in order not to offend anyone on the
net I invite you to send three blank disks to me directly at the address

below. I will load up the disks with all the items I have sent and were planning to send over the net and send the disks back to you. Therefore, the FONTS and fontloader, the FORTH, the SECTOR EDITOR, the UNSQUEEZER, the UUDECODER etc. will be on those disks.

I think this operation can work smoothly if I have your help - please include whatever packaging in which you want the disks sent back, make sure there is adequate postage on the package and don't forget your correct mailing address.

John Franco
2535 Spicewood Lane
Bloomington, IN 47401

Please note: you are taking a gamble sending me those disks - there is the chance they will be lost in the mail or damaged and I can take no responsibility for that. If three disks are too much of a gamble for you then send one disk and I will copy what I have sent out so far. If I become overwhelmed by the response I will raise a flag on the net indicating such.

P.S. A number of my reponses to mail messages were returned to me undelivered. If you were expecting to hear from me and didn't that is probably why. I think the above answers every one's questions pretty much.

Based on the stated requirements, I would suggest that you consider the
use of an Atari 800XL, at a cost of around $200 including monitor, rather than an
ST. I think it could do all of
the data collection and comparison
tasks you mention. To pursue this issue in more detail, and to avoid annoying
atari-16 types, you should put your question out on the info-atari8 net.

On the 800XL, the two joystick ports are a general-purpose PIA input/output with
four bits of the 8-bit PIA on each connector. You could connect a simple
interface there to multiplex between the different devices.

The 800XL also has a CPU bus connector on the back, so you can build more ambitious interfaces such as DMA ports to connect there.

The ST family has a DMA port but no direct CPU bus connection available. Certainly you could use either a 520ST or 1040ST to do your task, but it would seem like overkill. However, if you want to include high-resolution graphics displays of your measurement results, or do other calculations that require a lot of computing power, then the ST processors make a good deal of sense.

If you already have a TV set or composite monitor available, an 800XL can be obtained for about $70, which is a very inexpensive way to get a laboratory computer.

The 800XL is in fact very much in the class of computers used in the 60s and early 70s as lab systems, e.g. the PDP-8! In fact, with its 65K of memory, it is comparable to a very big PDP-8 system!

I am seriously considering, among other possibilities, purchasing a 1040st for use as a laboratory data collection/ analysis device. Before I can make up my mind, however, I need to get answers for a few questions.

1. Suppose I want to "read" several (five) 12 or 16 bit digital devices "simultaneously"; i.e. I want to move data from some external digital devices to (possibly sequential) RAM as quickly as possible. The devices should (or will) all be set prior to the read.

2. Suppose I want to output different data to several different digital devices "simultaneously"; i.e. I want to move data from preveously loaded RAM to external digital devices.

3. Suppose I want to read two digital devices, compare the data, and output another digital signal to a third device that depends on the result of the comparison. I want to do this FAST too.

I am willing to put together some hardware to do this. I think I can also manage the software, provided that this can be done at all. What I need to know is where do I "plug in" to get the fastest data flow rate. I guess I should say that I only want to do this once every second or so. Can I "wire" the devices as high order otherwise unused memory locations and then just move the data?

Any help, etc. etc. etc. Thnak you.

D. DeSmet
AAPH332@UA.BITNET

Thought for the day: I feel more like I do now than I did when I started writing this.

=-=-=-=-=-=-=-=-=-= line eater poison :-) =-=-=-=-=-=-=-=-=-=-=-=

I'm having some trouble getting STUSQ to do the right thing...
I used Kermit to get the uuencoded file off a Vax and ran it through
the ST uudecoder provided by franco@indiana.CSNET. When I try to run
STUSQ it appears to load, but then exits normally. This happens using
both CLI and the Desktop. I tried the SID68K debugging tool to see if
I could see where it was going and all I got was "Bus Error at 00049B50".
SID68K itself runs OK, but I get the Bus Error when trying to read STUSQ.

So, I thought I'd try DUMP'ing STUSQ to see if there were any ASCII
strings, just to check that the uudecode worked... Here's a few of the
strings I saw flash past:

```
cstrlen    f_open    f_close    f_read    f_write    f_lseek
gemalign   f_lseek failed       gemfread

You tried to write a read-only file!

Open needs 2 arguments - name and more

process-command-line

This implementation is nearly FORTH-83 standard, but it lacks
mass storage and uses 32-bit stacks

68000 Forth 83 - Atari 520 version
```

From this I think it's fair to assume that the uudecoder is working fine, but for some reason STUSQ won't load and/or run. I have a 520ST with TOS in RAM, monochrome monitor, twin single-sided disks and 512K of RAM. I am not currently using any RamDisk, so there should be enough spare RAM. Also, I have used ST uudecode on other things that worked...

Does anyone have any bright ideas ?? Do I need any particular TOS or other environment ?? Is STUSQ supposed to start with 120 zero words ??

All help gratefully received,

Ralph Mitchell

Summary: Keyboard Clock is Crystal controlled, not power line

The ST ikbd (intelligent keyboard) microcontroller derives its timing information from the crystal clock, not the power line frequency, so it will be the same world-wide.

I should point out that the ST power supply only provides DC voltages to ST power connector... so the ST's keyboard would not know what the power line frequency was.

It sounds like stdout is buffered. Try saying

```
    fflush( stdout );
```

before the getchar().

Does anyone know if ATARI offers any discounts (not that one is really needed)
to students ehn purchasing an ATARI 520 or 1040 ST ?

Please reply by e-mail if you know anything. Thanks.

I feel that it would be most appropriate to use the printer port on the ST. All lot of poeple don't realize that it is a bidirectional i/o port rather than just a parallel output port. Your application seems ideal for this. Using the Dma port ofcourse will be a lot more complicated software wise, and also i suspect hardware wise. Hope this helps.

Summary: sorta long flame regarding 1040s

In the hope that I can get a straight answer, or *something* approaching it...

I assume, from Erik Freed's postings ("our office just received 6 1040's") that on the west coast, there seems to be little trouble in getting 1040's. I've been waiting since early February

(when the machine was announced) with my name on my dealer's list. I read all about the arrival of the first shipment (yes, yes, by way of the Phillipines, I know all about that...), but still, to this day, neither my dealer, Data Control Systems of Cayce, SC, nor his "authorized distributor", Allison-Erwin Co. of Charlotte, NC, have even SEEN a 1040, much less sold one. Yes, the orders are stacking up, but all we get is "two more weeks... two more weeks... two more weeks... two more weeks".

Why the relative abundance of machines out west? And *NOTHING* out here? My dealer's experiencing a marked slowdown of 520ST orders because people are holding out for 1040's and he can't get them! He can't even get any TOS ROMs to upgrade the machines he has sold! It's possible that the distributor is using many of the ROM sets for his own field upgrades, but my dealer has even sent a direct order to Atari Corp. for ROMs. It's been 3 weeks since he did that, and still nothing. Meanwhile, a customer of his called Atari to gripe and they sent him a set of ROMs pronto...

I'm hearing rumors that Atari is trying to get dealers to order direct from them now and that to speed the process, they're *deliberately starving* the distributors out here who are crying for machines. That plan doesn't sit too well with my dealer, especially the "$3000 minimum order" that Atari enforces for direct orders...

I'm hoping that there isn't any truth to rumors like that. But when you've been waiting a few months, you begin to think "Well, maybe they *are* true, judging from current events..."

What do you say? I'd sure appreciate some answers, Neil.

Steve Wingard

I don't know of any character buffer, but if you want to write raw
characters to the screen (ie. so that the emulator does not intercept
them) you can write to Device 5 using something like Bconout .
Hope tht helps.

```

That is not a bug. Printf write to stdout which is a bufferwed stream.
So if you want the prompt to appear before the getchar() you will have
to flush the stream something like

```
     printf("Enter a Char:");
     fflush(stdout);
     c = getchar();
```

     I tried it just now, and it works.

I am very pleased with the INTERSECT ram disk that John Franco posted
a few weeks ago (Thanks, John). The deallocation feature is quite useful.

I have a question though. INTERSECT has a display of the free ram available for use as a ramdisk. Right after I boot (TOS on disk) the free ram shows around 175K. But if I list a file on the screen (by selecting SHOW in the window that appears when you select a non-executable file), the available ram is reduced to 130K the next time I look.

Does anybody know what is causing this?

Also, I've removed DESK1 and DESK2 from the boot disk to get more memory. Without DESK1 though, it appears that the changes I made to the desktop with the Control Panel are no longer invoked. DESKTOP.INFO is still on the disk. Is there any way to get a customized desktop to appear without installing DESK1?

Thanks in advance,

Bart Atwell

Get my multi-window terminal emulation from mod.sources. I have posted it
today, so it should be around in the next week. I don't scroll th screen but
scroll my internal copy of the window and update the visible portions
afterwards. Maybe it's not the fastest method, but it works well even when
a window is overlapped by four others.

     Hans-Martin

When I got my ST, I noticed that my disk drive power supply was
different than the others I've seen. My power supply is black and has
the cable coming out of opposite sides of the box. All the others are
grey and have cables coming out of the same sides of the box. The
cable going from the power supply to the disk drive is thicker on

mine, also.

Here's the question: I heard that the old system unit power supplies had surge problems. The way you could identify one of these power supplies is that the cables came out of opposite sides of the box! My system unit power supply seems to be ok, but should I worry about my disk drive? (I hadn't turned off my ST in about two weeks, and when I did, I had troubles booting).

Thanks.

Todd Fujinaka

     Could anyone tell me what bugs there are in the DRI C compiler? I am working on some GEM programs, and I keep getting bus errors (the ole' double mushrooms...). I couldn't think of anything I did wrong, so I atarted wondering about a bug in the compiler (Yeah...if the program doesn't work blame it on the compiler...I know.). In any case, the bus error comes in on a link instruction, which looks awfully close to a local variable init code. Is there any chance that the DRI C compiler has a frame problem somewhere? I would appreciate any info and possible fixes.

     Also, how have people approached window text scrolling? V_gtext is far too slow for a complete offset text redraw. I would like to do a bit scroll, but the GEM manual was very hazy on how to do this, and I am not sure if desk accessories on top of a window would screw up the bits when scrolled. I actually would like a scroll rectangle call like on the Macintosh, that gives redraw messages for the scrolled area under the desk accessory. Any help here would also be great...

Thanks,

--- Bri

Hi,

I am sorry if this has been discussed before, but I am new to this newsgroup.

Could someone point me to any benchtest results for various C compilers for the
ST.

I would also be interested to here peoples views on their experience of C
compilers for the ST. The areas of interest are speed, object code size, and
UNIX compatibility.

Many thanks,

Andrew Smith.

The main problem with uudecode on several systems seems to come from truncated
lines with originally blank characters at the lineend. The lines have to be
extended with blanks to the length defined in the 1st character of the line.

With the exception of the first uuencoded posting of micro-emacs, I've
had no difficulty in getting the uuencoded stuff to run on my ST. In

case you are curious, I have been using the uudecode on our UNIX (tm, etc. :-)
system - not the uudecode posted a while back to run on the ST - and
then downloading the binary files to my ST using XMODEM protocol.

For those who don't get too uptight about "Public Domain", the "breakout"
program is, I believe, the one that COMPUTE! mentioned which is on the
developer system disk and which lets you get your hands on the operating
system without GEM on top of it. MSDOS, CPM, or whatever, this is how you can
get at it! (The knowledgeable please comment.)

I just got my developers kit, and so have at last started to play with my ST.
A few bugs and annoyances have cropped up, so I thowght I would share them
with the net.

My hardware configuration is:
        Vanilla 520ST   (no 1meg upgrade, no TOS in ROM, ...)
        One Single-Sided and one Double-Sided floppy drive.
        Both B/W & RGB monitors (although only one at a time, sigh...)

    o   Eight-Character folder names do not seem to work. I created B:\EXAMPLES\
        and tried to move APSKEL.C and ACCSKEL.C into it. All I got was an error
        message saying "This application is unable to open the folder you named".
        Everything worked just fine if the folder name was B:\DOC\

    o   BATCH.TTP gives up at once (with no error messages) if you supply less
        parameters then it expects. I had created a generic batch script to
        compile, load, and run a C program. As the C program took parameters I
        had a line in the batch script of the form "B:%1.PRG %2". When I tried
        to use this same batch script to test another C program which did not
        take parameters I only supplied the first parameter, and BATCH.TTP gave
        up after printing its banner line. Supplying a dummy second parameter
        made BATCH.TTP happy.

 * o   There is no easy way to make a double-sided bootable system disk.
        The only way I can see is to write a C program myself to create a
        boot sector on the disk.

 * o   It would be really nice if there was a simple application to display
        a source file. I know that MicroEmacs will let me look at a file, but
        I would really like to be able to scroll through a document using
        scroll bars!

If anybody has source code for either of the last two items (flagged with *)
I would love to hear from them. If not, then when I get round to writing them
myself I will post the sources to the net.

You probably haven't yet removed the desk accessories. They take up bunches
of memory, and if the ST doesn't have enough memory to run a program, it
just returns to the desktop. Make a copy of your system disk and remove
anything ending with ".ACC", then boot up with that disk and try again.

TOS was a total rewrite, NOT a modification of CP/M-68K in any form nor
fashion, no sources were the same, different from the ground up. And DRI
did it.

Organization: AT&T Information Systems Labs, Denver, Co
Lines: 16
Keywords: XMODEM, uudecode

I found the problem with using uuencoded files. I wrote my own file
download program (XMODEM) and it dropped a sector (128 bytes) every time
the record counter wrapped from 255 to 0. Needless to say, downloaded
files could not be expected to be decoded properly. Since then, I've
modified my receive program to handle binary files (how I found the bug)
as well as text and I run uudecode on VAX. When downloaded, the binaries
run fine (except two of us have not had any luck with getting as68.ttp
to run).

Sorry for raising a false alarm.

The biggest problems I've found with DRI C is that it is VERY
sensitive to parameters matching. I've found several programs
I've ported from MS-DOS that work happily there but give me mushrooms
on the ST. So far, the problem has ALWAYS been mismatched parameters.

You have to pass ints to ints, chars to chars, and pointers to pointers.
(and longs to longs!). Any mismatch, and bye bye. Hope that helps.

There is a bug in the terminal description for the ATARI ST
in the version of TVX just posted to mod.sources. In file
tvx_term.ic, in the definition for the Atari (#ifdef ATARI520),
change the one line:

```
    EXTERN char cdelchr[8]={27,'M',0,0,0,0,0,0};   /* delete char on screen */
```

to:

```
    EXTERN char cdelchr[8]={0,0,0,0,0,0,0,0};  /* delete char on screen */
```

This was caused by trying to maintain source for too many machines! I
just didn't get the real atari entry back up to the vax before I posted.
Sorry about that! The bogus entry will cause TVX to erase the entire
line rather than just one character. Zeroeing it makes the code use
a different delete character algorithm. The delete character code is
new from the January posting, and really helps on dialups. The change
is insignificant on fast screens.

A new improved version of TVX with vi and emacs emulation,
as well as its native command set, has just been posted to mod.sources.
If you don't get mod.sources, please contact me directly for methods
on getting the source. The first bug notice (relating to the ATARI
version only) was also posted to net.sources.bugs.

Documentation for
Gordo's MC68000 Tiny BASIC version 1.0

This is an adaptation of Li Chen Wang's 'Palo Alto Tiny
BASIC' for the Motorola MC68000 microprocessor. It includes more

functions and program save and load. As distributed, it is set up for a Motorola MEX68KECB Educational Computer Board connected to a host CP/M computer. The source code should give you enough details to allow you to install it on a different system. If you have any problems, you can write to me at:

Gordon Brandly
R.R. 2
Fort Sask., AB, Canada
T8L 2N8

This version for the Atari 520 ST translated by :

Kenneth L. Hurley
1230 W 7th #3
Eugene, OR 97402
(503) 343-7285

The Language

Numbers

In this Tiny BASIC, all numbers are integers and must be in the range 2147483647 to -2147483648.

Variables

There are 26 variables denoted by the letters A through Z. There is also a single array @(I). The dimension of this array (i.e., the range of value of the index I) is set automatically to make use of all the memory space that is left unused by the program (i.e., 0 through SIZE/4, see SIZE function below). All variables and array elements are 4 bytes long.

Functions

There are 4 functions:

ABS(X) gives the absolute value of X.
RND(X) gives a random number between 1 and X (inclusive).
SIZE gives the number of bytes left unused by the program.
PEEK(X) gives the value of the byte at memory location X.

Arithmetic and Compare Operators

/ Divide. (Note that since we have integers only, 2/3=0)
* Multiply.
- Subtract.
+ Add.
> Greater than. (comparison)
< Less than. (comparison)
= Equal to. (comparison) Note that to certain versions of BASIC "LET A=B=0" means "set both A and B to 0". To

this version of Tiny BASIC, it means "set A to the result of comparing B with 0".

<>	Not equal to. (comparison)
>=	Greater than or equal to. (comparison)
<=	Less than or equal to. (comparison)

+, -, *, and / operations result in values between -2147483647 and 2147483647. (-2147483648 is also allowed in some cases.) All compare operators result in a 1 if true and a 0 if not true.

Expressions

Expressions are formed with numbers, variables, and functions with arithmetic and compare operators between them. + and - signs can also be used at the beginning of an expression. The value of an expression is evaluated from left to right, except that * and / are always done first, and then + and - , and then compare operators. Parentheses can also be used to alter the order of evaluation. Note that compare operators can be used in any expression. For example:

```
10 LET A=(X>Y)*123+(X=Y)*456+(X<Y)*789
20 IF (U=1)*(V<2)+(U>V)*(U<99)*(V>3) PRINT "Yes"
30 LET R=RND(100), A=(R>3)+(R>15)+(R>56)+(R>98)
```

In line 10, A will be set to 123 if X>Y, to 456 if X=Y, and to 789 if X<Y. In line 20, the "*" operator acts like a logical AND, and the "+" operator acts like a logical OR. In line 30, A will be a random number between 0 and 4 with a prescribed probability distribution of: 3% of being 0, 15-3=12% of being 1, 56-15=41% of being 2, 98-56=42% of being 3, and 100-98=2% of being 4.

Program Lines

A Tiny BASIC line consists of a line number between 1 and 65534 followed by one or more commands. Commands in the same line are separated by a colon ":".

"GOTO", "STOP", and "RETURN" commands must be the last command on any given line.

Program

A Tiny BASIC program consists of one or more lines. When a direct command "RUN" is issued, the line with the lowest number is executed first, then the one with the next lowest line number, etc. However, the "GOTO", "GOSUB", "STOP", and "RETURN" commands can alter this normal sequence. Within a line, execution of commands is from left to right. The "IF" command can cause the remaining commands on the same line to be skipped over.

Commands

Tiny BASIC commands are listed below with examples. Remember that multiple commands can be put on one line if colons separate them. In order to store the line, you must also have a line number at the beginning of the line. (The line number and multiple-command lines aren't shown in the examples.

REM or REMARK Command

```
REM anything goes

This line will be ignored by Tiny BASIC.
```

LET Command

```
LET A=234-5*6, A=A/2, X=A-100, @(X+9)=A-1
```

Will set the variable A to the value of the expression 234-5*6 (i.e. 204), set the variable A (again) to the value of the expression A/2 (i.e. 102), set the variable X to the value of the expression A-100 (i.e. 2), and then set the variable @(11) to 101 (where 11 is the value of the expression X+9 and 101 is the value of the expression A-1).

```
LET U=A<>B, V=(A>B)*X+(A<B)*Y
```

Will set the variable U to either 1 or 0 depending on whether A is not equal to or is equal to B; and set the variable V to either X, Y or 0 depending on whether A is greater than, less than, or equal to B.

Print Command

```
PRINT
```

Will cause a carriage-return (CR) and a line-feed (LF) on the output device.

```
PRINT A*3+1, "abc 123 !@#", ' cba '
```

Will print the value of the expression A*3+1 (i.e. 307), the string of characters "abc 123 !@#" and the string" cba ", and then a CR-LF. Note that either single or double quotes can be used to quote strings, but pairs must be matched.

```
PRINT A*3+1, "abc 123 !@#", ' cba ',
```

Will produce the same output as before, except that there is no

CR-LF after the last item printed. This enables the program to continue printing on the same line with another "PRINT".

PRINT A, B, #3, C, D, E, #10, F, G

Will print the values of A and B in 11 spaces, the values of C, D, and E in 3 spaces, and the values of F and G in 10 spaces. If there aren't enough spaces specified for a given value to be printed, the value will be printed in full anyway.

PRINT 'abc',_,'xxx'

Will print the string "abc", a CR without a LF, and then the string "xxx" (over the "abc") followed by a CR-LF.

INPUT Command

INPUT A, B

When this command is executed, Tiny BASIC will print "A:" and wait to read in an expression from the input device. The variable A will be set to the value of this expression, then "B:" is printed and variable B is set to the value of the next expression read from the input device. Note that whole expressions as well as numbers can be entered.

INPUT 'What is the weight'A, "and size"B

This is the same as the command above, except the prompt "A:" is replaced by "What is the weight:" and the prompt "B:" is replaced with "and size:". Again, both single and double quotes can be used as long as they are matched.

INPUT A, 'string',_, "another string", B

The strings and the "_" have the same effect as in "PRINT".

POKE Command

POKE 4000+X,Y

This command puts the value produced by expression "Y" into the byte memory location specified by the expression "4000+X".

CALL Command

CALL X

This command will call a machine language subroutine at the address specified by the expression "X". All of the CPU's

registers (except the stack pointer) can be used in the subroutine.

IF Command

IF A<B LET X=3: PRINT 'this string'

This will test the value of the expression A<B. If it isn't zero (i.e. if it is true), the rest of the commands on this line will be executed. If the value of the expression is zero (i.e. if it is not true), the rest of this line will be skipped over and execution continues on the next line. Note that the word "THEN" is not used.

GOTO Command

GOTO 120

Will cause execution to jump to line 120. Note that the "GOTO" command cannot be followed by a colon and other commands. It must be ended with a CR.

GOTO A*10+B

Will cause the execution to jump to a different line number as computed from the value of the expression.

GOSUB and RETURN Commands

GOSUB 120

Will cause execution to jump to line 120.

GOSUB A*10+B

Will cause execution to jump to different lines as computed from the value of the expression A*10+B.

RETURN

A RETURN command must be the last command on a line and must be followed by a CR. When a RETURN command is encountered, it will cause execution to jump back to the command following the most recent GOSUB command.

GOSUB's can be nested with a depth limited only by the stack space.

FOR and NEXT Commands

FOR X=A+1 TO 3*B STEP C-1

The variable X is set to the value of the expression A+1. The values of the expressions (not the expressions themselves) 3*B and C-1 are remembered. The name of the variable X, the line number and the position of this command within the line are also remembered. Execution then continues the normal way until a NEXT command is encountered.

The step can be positive, negative or even zero. The word STEP and the expression following it can be omitted if the desired step is +1.

NEXT X

The name of the variable X is checked with that of the most recent FOR command. If they do not agree, then that FOR is terminated and the next recent FOR is checked, etc. When a match is found, this variable will be set to its current value plus the value of the step expression saved by the FOR command. The updated value is then compared with the value of the TO expression also saved by the FOR command. If this within the limit, execution will jump back to the command following the FOR command. If this is outside the limit, execution continues following the NEXT command itself.

FOR's can also be nested with a depth limited only by the stack space. If a new FOR command with the same control variable as that of an old FOR command is encountered, the old FOR will be terminated automatically.

STOP Command

STOP

This command stops the execution of the program and returns control to direct commands from the console. It can appear many times in a program but must be the last command on any given line, i.e. it cannot be followed by a colon and other commands.

BYE Command

Will return you to the resident monitor program or operating system. (Tutor in the case of the ECB.)

Direct Commands

As defined earlier, a line consists of a line number followed by commands. If the line number is missing, or if it is 0, the commands will be executed after you have typed the CR. All the commands described above can be used as direct commands. There are five more commands that can be used as direct commands but

not as part of a program line:

RUN

Will start to execute the program starting at the lowest line number.

LIST

Will print out all the lines in numerical order.

LIST 120

Will print out all the lines in numerical order starting at line 120.

NEW

Will delete the entire program.

SAVE

Will save the present program on the storage device you provide. Details on installing this device are given in the source code. As set up for the MEX68KECB Educational Computer Board, this command will send the program out to the host computer in an easily-stored text form. It isn't, however, pure program text as the line numbers are stored in hexadecimal.

LOAD

Will delete the program in memory and load in a file from your storage device.

Stopping Program Execution

The execution of the program or listing of the program can be stopped by pressing the control-C key on the console. Additionally, a listing can be paused by pressing control-S, and then pressing any key to continue.

Abbreviations and Blanks

You may use blanks freely within a program except that numbers, command key words, and function names cannot have embedded blanks.

You may truncate all command key words and function names and follow each by a period. "P.", "PR.", "PRI.", and "PRIN." all stand for "PRINT". The word LET in LET commands may also be omitted. The shortest abbreviations for all the key words are as follows:

```
A.=ABS    C.=CALL   F.=FOR    GOS.=GOSUB     G.=GOTO
IF=IF     I.=INPUT  L.=LIST   LO.=LOAD       N.=NEW
N.=NEXT   P.=PEEK   PO.=POKE  P.=PRINT       REM=REMARK
R.=RETURN R.=RND    R.=RUN    S.=SAVE        S.=SIZE
S.=STEP   S.=STOP   TO=TO
no key word = LET
```

Error Reports

There are only three error conditions in Tiny BASIC. The line with the error is printed out with a question mark inserted at the point where the error is detected.

(1) "What?" means it doesn't understand you. For example:

```
What?
260 LET A=B+3, C=(3+4?. X=4
```

(2) "How?" means it understands you but doesn't know how to do it.

```
How?
210 P?TINT "This"   <- where PRINT is misspelled

How?
310 LET A=B*C?+2    <- where B*C is larger than 2147483647

How?
380 GOTO 412?       <- where 412 does not exist
```

(3) "Sorry." means it understands you and knows how to do it but there isn't enough memory to accomplish the task.

Error Corrections

If you notice an error in your entry before you press the CR, you can delete the last character with the backspace (control-H) key or delete the entire line with control-X. To correct a line, you can retype the line number and the correct commands. Tiny BASIC will replace the old line with the new one. To delete a line, type the line number and a CR only. You can verify the corrections to line 'nnnn' by typing "LIST nnnn" and pressing the control-C key while the line is being printed.

Distribution: net
Organization: Advanced Programming Resources, Columbus OH
Lines: 89
Keywords: Lattice-C ST-development
Summary: Lattice-C is now AVAILABLE

<Eat this line and call me in the morning>

I've purchased and am now using the Lattice-C compiler for the ST...
What follows is a brief review:

Product: Lattice-C compiler

Developer: MetaComCo plc
        26 Portland Square
        Bristol, BS2 8RZ
        England

        5353 Scotts Valley Dr.
        Scotts Valley, CA 95060

List Price: $149.00

Included: Compiler (Two files -- Seperate passes)
(Brief)   Driver Program (Short-hand, runs the two passes together)
        Editor -- screen with command mode
        Linker (GST)
        C Library (Both GST and LINK68 formats)
        GEM interface library (Both GST and LINK68 formats)
        GEM interface library source (MetaComCo Macro Assembler format)
        Manual -- Paperback (270 or so pages)
        3.5" SS/DD Disk
        Bookshelf case
        Warranty/Registration card

Compiler: The compiler is a fairly complete implementation including
        bitfields, floating point, unsigned char, and the like.
        Preprocessor is a little limited (No good expression
        processing using defined symbols in #if lines.) The code
        generated seems to run quite well, but the linked program
        is slightly larger than the same code compiled with the
        Alcyon (DRI) C compiler and the library supplied with the

toolkit. For MicroEmacs (my version) the difference is about 3K (36000bytes vs 33000bytes), but the library with Lattice C seems to be more robust. The compiler has options to generate DRI format files, to specify A6 or A5 for frame pointers, and position-independent code.

Library: Not the fullest library, but adequate. The memory allocation routines have a weirdness about them -- By default, the program snarfs up all but 4K of the available space on the system, but you can specify, either at compile/link or run time, just how much space you want available for malloc. This is not bad if you don't want to execute child processes or are not going to use an undetermined amount of dynamic memory -- This switch would be nice if you could specify how much memory to leave available to the system rather than requiring you to specify the amount of pool to allocate. Anyway -- There is no realloc(), getenv(), or access to the "Line A" interface. There are extensive, and useful, string functions including pattern search. The GEM library is complete, so far as I can tell. The libraries are provided in both GST and DRI format. Source for the GEM interface library is included.

Linker: Does what it says. This is the GST linker. Uses command files which are easy to understand. Well documented. Produces link map files (can be supressed.) Allows definition of globals at link time including simple arithmetic using globals from object modules. Reasonably fast.

Documents: Clear, concise and well layed out. Seems to be hastily put together, though, lacking good examples. Appendix D, the function index, is from the MS-DOS Version for the 8086. Would be more convenient in loose-leaf form.

Summary: For the price (I got it for about $105.00) this seems to be a good choice. It compiles faster and produces more robust code than the Alcyon compiler. If you intend to use GEM from a program, a GEM programmers manual would be useful.

Disclaimer: Other than being a customer, I've no association with ATARI, MetaComCo, Digital Research, or anybody else with any clout. Everything is a registered trademark of someone or another -- Don't blame me -- I didn't do it, I just look guilty.

Keywords: ramdisk, Atari ST

Here is a silly little ramdisk that is being placed in the
public domain. Cut carefully at the dotted line, bring it
down to your ST, assemble it, link it, relmod it, and you're
on your way. Install it by double-clicking it, or put it
in the \AUTO folder and forget about it. It installs itself
as device M:.

```
- - - - - - - - - - - - cut here - - - - - - - - - - - - - - - - - - - - - -
* ramdisk.s

*--------------------------------------------------------------------------

I have had similiar problems with folders with names equal to 8 chars. The
difficulty even extends to not being able to delete any folder with an
8 character name.

There is an easy way to create a double-sided bootable system disk. A
utility is already available called WBOOT.PRG and it is listed in the
bloomington st users group PD software catalog that they publish here
on the net 03/10/86.

i have the same problem (more or less) when i try to download from a
host, it works fine uploading. playing around with the delay
parameter on the host (making it shorter) seems to help.

get rid of that old power supply, i have had nothing but trouble
with my ST until they traced the problem to the power supply and
gave me a new one (both cables on the same side).

the COMMAND.PRG that came with my developer's kit has several undocumented
commands. There are others that I have forgotten, or don't understand.
Also, there are unix synonyms (LS CAT MV etc). To see them all, look in
COMMAND.PRG.

```
  TYPE filename             -- display on screen as text
  COPY from-file to-file    -- copies one file
  RENAME from-file to-file  -- renames one file (to same folder only)
  DIR wild-name             -- list matching files
  DEL filename              -- deletes a single file
  MD directory-name         -- Creates a folder
  RD directory-name         -- deletes a folder
  CD directory-name         -- path to a folder
  CD ..                 -- path to parent folder
```

*** NOTE ***
  none of these are recognized by BATCH.PRG

This can happen if you uudecode first, and then transfer the files with
kermit without using image mode. Then extra characters get inserted in the
binary, and anything can happen.

I really like the 1040ST except for one thing - I can't stand the keyboard!
I would buy a 1040ST if I could get a full travel type keyboard to replace
the standard keyboard ... does anyone know of such a product? Or of a way
to improve the touch on the standard keyboard?

There ARE bugs in the Alcyon compiler (the one in the Atari developer's kit),
but they mostly have to do with automatic type conversion to/from LONGs.
Occasionally it actually ignores a line for no apparent reason (I hate it
when that happens). It's very rare, though. Either you ran out of stack
space, or it's an error in your program. I've never gotten a bus error using
the Alcyon C compiler and traced it to the compiler.

If you're running a desk accessory or filling out a form or a dialog box or
something similar, then no background processes are running. If you have
an active window (hence, on top), you can use the "Copy Raster, Opaque"
call (vro_cpyfm) to just BitBLT the window up one character height (said
height can be gotten from Inquire Current Face Information [vqt_fontinfo])
and another BitBLT to clear out the last row.

       325 lines of uuencoded data follow.

A Suggestion:

  One can easily see how net.sources (and perhaps the net in general) has dropped in quality over the past year or so. (if your site archives net.sources just have a look at all the subject lines, Waterloo just recently culled its archives and the results were not impressive.)

This particular newsgroup has been very informative and it would be a shame to see it degrade to the point where it became a forum for posting binaries and follow the pattern of net.micro.mac (which has now become 3 newsgroups, mod.mac.binaries, net.sources.mac, and net.micro.mac).

The suggestion is merely this:

  If you have a binary to distribute, in whatever form, you post your e-mail address (with alternate routes) to net.micro.atari16 to announce its availability.

Interested parties can then use mail to request a copy from the author.

  Personally I would prefer that only source gets posted. Yes not everyone has a developers kit, yes mail fouls up, and yes, source never seems to

compile correctly on your particular system/compiler, but it is much
more enlightening for the reader to see how someone has done something,
and it reduces the net traffic.

  But consider, how many people who have access to usenet don't also have
access to someone with a compiler for the ST (either friends or on a BBS),
and how often, as has happened with hack, has one source distribution
for a particular machine/compiler proliferated onto several different
machines/compilers.

  Posting binaries distributes programs, posting source distributes
knowledge, and knowledge helps to make more programs for everyone!

I don't really expect the above appeal to make any difference but...
one lives in hope.

This may be obvious to you or not, but it is important and of general interest.

The DRI C compiler uses 16 bit ints, and 32 bit pointers (only 24 bits
significant). Having worked with another such compiler (also 68K), there
are a few "gotchas" to worry about. In particular, even though you may
have casted, cleaned, and linted (unix 'C' verifier) your code, it can
still go crazy. I had a similar link problem when passing a pointer as
an int, going the other way can cause problems on the return. Of course,
a pointer casted as integer loses significant bits, and casting the other
way can either be sign extended (used to force a crash), or trunkated,
which can do interesting things if the code is modified.

For some of the other "gotchas", look at some of the archives in net.lang.c

This is "acceptable" behavior, but other compilers using 32 bit ints
are more predictable (and slower). The DRI version is faster, but code

needs to be very carefully checked.

>software houses write their programs if the target machines are constantly
>changing.

Software is the easy part, if programs are written in a kosher Application/OS fashion, the trap vectors will provide transparency between the application and the hardware. These "rumors" are a simple warning, "cute code" is unconditionally unacceptable. If the code tries to "capture" the operating system, it will be obsolete. Drivers might be sold as drivers, but to make them integral to the application (ALA 1-2-3, EA,...) is a good way to exclude new markets as they arrive.

>There are now two STs (all within a few months) on the market
>with at least one (with more ram) and/or another (with graphics co-processor)
>machine(s) in the wings (that's what Atari have told us about anyway). I
>believe in progress sure, but every time I go to order an ST there is
>talk/rumour of a new model, (Yes I have not purchased an ST yet!).

My biggest concerns are hardware upgrade path and industry compatibilty.
You can do major surgury on a 520 to make it a 1040, but new 520's don't
seem to be any easier to expand, and neither have a good clear "Co-processor"
interface. The CPU's are still soldered directly into the box. The other
concern is the DMA bus. Atari knows about SCSI, supports the protocol, but
seems determined to stick with their own bus (Not SCSI compatible). This
is the same attitude that Commodore/Atari used on the old machines. I may
go ahead and buy a "K-Mart ST" because I like most of what they did, but
I don't want to invest in a bunch of "Atari only" peripherals, no matter
how cheap they get (well maybe a $100 CD-Rom). I would be willing to
"gamble" on a peripheral with a standard interface. If some other
company, or Atari for that matter comes up with a better price/performance
machine with the same interface, the old ST can go to the kids, but the
hard drives are still usable.

Some questions of my own:
In the interview, a 1024x1024 display was mentioned. The ST seems to have
the bandwidth to support this at 70hz interlaced, is it a software hack,
or is new hardware required?

When is the PC industry gonna "Grow up" and adopt even minimal standards?
Does IBM have to do everything??!!!

You don't! You must go to the BIOS to get to the interrupt that lets you change the color palette on the fly.

>   2) Are there plans for a compiled basic in
>   the forseeable future?

Philon is planning to market one under the name "Fast BASIC".

>   3) I can only get sound channel #1 to work. How do I get
>   the other channels to work?

Use the WAVE command to turn on the additional channels before using the SOUND command. WAVE 7,0,0,0,0 will do the trick.

> I suppose all these questions should be prefaced with the more
> general question: when is a newer release of the basic expected?

We are working on one. Perhaps within the next 2 months we will see one.

I know that the monitor which comes with the Amiga has inputs which let one use it as TV (with a VCR supplying the input, for example), and I know that the ST monitor does not have such an input (I believe it's called "composite").

My question is: is there hope for Atari users? Is there any device which will turn composite video/audio into RGB plus audio, as the SC1224 needs?

Well, another week has gone by and I still don't have a working 520ST.
It has been in repair since January 16th.

Would you believe that I sent the computer and power supply together
along with a note stating the power supply was blown and they only
fixed the computer. They sent me back a fixed (?) 520 and the same
blown power supply. Thank goodness I checked the power supply before
plugging it into the computer.

I now have to send back the power supply and they will send back a new one.
Note, I MUST send mine back first even though I was told the old black
one will be replaced (supposedly they have a design problem that causes
+5 to go to +15V). Therefore I assume it will take another week
to get another supply, assuming they are available.

A word of advise. I have been told that if you have the old black "brick"
power supply for the 520ST (P/N CO70099-3) you can be in the same situation
as me. There is a design problem that can cause the +5 volt supply to
provide +15 volts. This extra voltage does not make the computer work
three times faster (3 X 5 = 15). It puts you in the same position
I am in. Your computer will have to take a trip to the local repair
shop for an extended vacation, hopefully not > 2 months as in my case.

The advise I've been given is to get ATARI to replace your old power
supply with the newer model. Supposedly the old supply is a disaster
waiting to happen. Again, let me emphasize I am repeating what
I was told. This is not my opinion and do not claim originality
for these claims.

Please read your loader documentation again. Hex 0007 means the corresponding instruction word is the first word of an instruction. I forget what 0000 means, but I believe it indicate a following word of the same instruction that needs no relocation.

Stephen Leicht of the Technical university of Darmstadt has requested information on how to UUENCODE and UUDECODE files. Since I cannot figure out how to send that info to him directly and since many others are probably

curious I am posting this info to the net. Here it is:

  From isrnix!apratt Wed Jan 8 23:52:00 1986
  Date: Wed, 8 Jan 86 21:12:31 EST
  From: Allan Pratt <isrnix!apratt>
  Received: by isrnix.UUCP; id AA19728; Wed, 8 Jan 86 21:12:31 EST
  To: iuvax!franco
  Subject: uuencode
  Status: R

  I admit it's a little strange... uuencode is intended for use
  by mail programs, not by human beings. To encode a file called
  "foo", type

     %uuencode foo foo > foo.encoded

  and it will create a file called foo.encoded on your directory.
  (You can use any name you want after the >, except the name
  of your input file). To decode foo.encoded back into foo,
  type

     %uudecode foo.encoded

  and it will create foo. But remember that you have to have
  uudecode on the destination machine (like your ST) or it won't
  do much good.

     You ought to be ashamed for mentioning it, then. THe
fact that you got "special" favors, hush-hush, and then mentioned
them will probably ensure that you not receive such favors in the
future. Having admitted that you got them, now why don't you
let the rest of us know what they are???

<Mmmmmm, tasty>

I just installed Landon Dyer's PD ramdisk tonight. It works admirably, but
I thought I'd pass along some installation tips so you folks don't waste as
much time as I did. The instructions say to assemble, link, and relmod the
program. Do just like he says, but for the link, do something like:

     link68 [u] ramdisk.68k=ramdisk

This will link the ramdisk without the GEM or desk accessory stuff. It won't
work with that stuff included. I discovered the problem when I used a public
domain "cc" program to do everything, and it assumed I was linking a normal
program which needs all the GEM junk linked in. The linker whimpered about
_main being undefined, and the program got two 'shrooms when I tried to run
it. I got the same results when I tried to link in the desk accessory stuff.
Landon's program doesn't need all that stuff the rest of us mortals take for
granted.

Subject: Secret message in TOS?!
TO: All, but you especially Neil...

Hey, someone at Atari do me a favor
and give my regards to Dave and Bea.

    Everyone here at the Club Network
would like to wish them the best of
luck in their future. We also congratulate
them on the public nature of their
commitment in the form of "Dave Stagas
loves Bea Hablig" in the middle of
new TOS!

     All the hard core programming staff
would like to also give someone an "A"
for effort in getting these few ASCII
characters out under Atari's nose and
into the hands of the general public.
I mean, it sure beats Jack's face in the
character set!

    Give 'em a hand folks, we need more
of this kind of thing as OSes get
bigger and bigger! It's a good laugh
after a few long hours and sore eyes
of staring at numbers to get a "message"
from someone "out there!"

    As a note: We found this creative
message on our new TOS disk with the
TTOOL.ACC accesory. As I do 1 meg
upgrades, I dearly love it and someone
mentioned somewhere that it could
stand to be polished. Well if someone
will get me the source code I would
be happy to work on it. We found a
handful of little bugs just today. If
anyone knows where it came from, pass

the word.

   And I hope everyone else enjoyed our
"TOS (Two 'Oltime Sweethearts) Trivia"
section for the day!

I most strongly disagree with the author of the previous note. I think
most people are very interested in receiving any useful software that is
available. i think there is room for both code and talk on this net.
However, if alot of people want source listings stopped then so be it.
I am sorry to say that the suggestion of emailing code is unacceptable
to me as the cost is too high and the number of people benefitting is too
low.

A UUENCODED STSQUEEZED Public Domain FORTH in four parts has been
posted to net.sources. You need to reassemble the four pieces in order
(e.g. cat for1 for2 for3 for4 > forth) then UUDECODE then use the
ST unsqueezer.

Can anyone tell me what exactly a RAM cache is. I am the person who
originally made the 520ST RAMdisk, and am thinking about also making a
RAMcache if such proves usefull. However, I have never seen one (though
I can guess a lot) and need some ideas on the functionality.

What I guessed is :
  write through (keep disks updated)
  cache on read miss
  cache on write

  adjustable size cache

What I don't know is :
  do you want it to be completely invisible (no commands)
  how pessimistic should it be about disk exchanges

I can imagine the usefullness of such a tool. However, you still also need
a smaller RAMdisk, since a lot of time goes into write & verify of intermediate
files for C compilers etc.

Any experience and suggestions please DIRECTLY to me, I'll summarize on the
net.

I agree. It would be much nicer if when you double clicked a file, instead
of getting that terrible 'more', you just got a window on the file which you
could scroll. And that warning thet you can only show or print the file is a

pain too. It would be nicer to select the icon, and then select a print menu item.

> If anybody has source code for either of the last two items (flagged with *)

What would be very nice is a version of MicroEmacs that opens real windows instead of imitating them like it does. Then you could use the scroll bar instead of ^V, ^X-^N, etc.

Another point altogether: some of the example programs use routines beginning rc_. An example is apskel.c which uses rc_intersect to see if two rectangles overlap. I can't find these documented anywhere (or even mentioned in any header file). Anyone got any documentation? Has anyone already dismembered the libraries to see if there are any other goodies hiding in there, and would like to share it with us?

Well, if it's the same as the C64 version, you can (o)ffer the shopkeepers
money, but you won't get anything from them. The only way I know to get
food is to go to a food shop (they have names like McDonald's or Alfred's
Fish and Chips). Not every town has a food shop. Try looking in different
towns.

Did I hear someone say he needed a way to write boot sectors onto disks?
I have posted the UUENCODED wboot.ttp to net.sources for your information.
Only catch - I haven't used it yet so I can't give advice on it.

I think I figured out what happened to the UUENCODED microemacs binary I
posted earlier - I think UUENCODING it resulted in a file that was too big
to be transmitted in its entirety. I will soon repost in two pieces.
Is everyone happy if I post to net.sources?

A utility for writing boot sectors to double sided disks is posted
in net.sources just a few postings away from the single sided write boot
sector utility. The program is supposed to be user friendly - it prompts
for the single sided then double sided disks.

The main problem with uudecode on several systems seems to come from truncated
lines with originally blank characters at the lineend. The lines have to be
extended with blanks to the length defined in the 1st character of the line.
A slightly corrected version of uudecode.c can be sent if needed.

>speed, but I had heard that the hard disk controllers were actually
>running at 7.5Mbits or 5Mbits.
...
The developers drives have two boards in - a standard hard drive controller,
and a bus convertor board. I was told around Christmas time that before
selling commercially, Atari wanted to get this onto one board, and into a
plastic case, so your dealer is on the right lines. 5MBits is the quoted
rate for the drive, but some timings I made using an analyser (very rough)
suggested the acknowledges were closer to 7MBits. If Atari wish to use a
single board, then the new board may be faster. The developer setup looks like
a standard SASI board, with a SASI to Atari convertor (one PAL, about 6 TTL).

>   Anyway, back to hard disks... the developers hard disk I
>   looked at had a fan that seemed to be about average for
>   fan noise.)

Yes - average, fine by me.

>
>Other differences of more minor interest would include requirements for
>parking the heads. I understand that the developer's hard disk requires
>this, but I can't imagine that a commercial version would.

There is a utility to move the heads to a safe landing point (!) for
transport. The importance is not heavily stressed, just suggested.

I have posted a two part microemacs binary to net.sources. You must
concatenate the two files, strip away the lines put in by the mailer
(at the beginning and end of each file) , UUDECODE and ST UNSQUEEZE.

Woops...it appears that something adds lines at the beginning and end
of each transmitted file. therefore, you must strip away the added lines
after concatenating (it is best to do it then since it is easy to search
for the added lines (they are very distinctive) and when you get it all
fixed you will know it - if you strip away the lines before concatenating
you might get an extra newline character or you might be minus a newline
character when you concatenate (of course you can go in later to check this
but then you don't have a good way of finding precisely where the files
were joined))

I just took all four parts of PDFORTH from net.sources, cated them,
applied emacs to take out the extra lines, UUDECODED the result,
downloaded to my ST and ST UNSQUEEZED. Believe it or not - it worked.

I did have one minor problem, though - I couldn't get the unsqueezer
to work in the RAMDISK. But, running it from drive A succeeded (with
the file pdforth.tqs on the ramdisk).

I have heard that you can upgrade a 1040ST to 4 Meg by swapping the
256K RAM's out and putting in 1 Meg RAM chips. Anyone know if this is true?
Also, is there any difference in external expansion connections on the
1040 vs the 520?

We received 6 1040ST's here at Aurora and At least two of them developed
problems with the internal floppy disk drive. After a while the disk has
trouble accessing the disk and makes awful whining/grinding noises. I
solved this on one machine by changing the resonant frequency
of the head assembly which seemed to be oscillating something fierce.
So far I have done this by tacking a wad of masking tape on the head.
Obviously this is temporary. My question is: Has anyone experienced
and possibly solved this in some cute/easy way? I like the machine and
would rather not send it back for something seemingly easy to fix.

HELP!

I am trying to get a Mitsubishi 5.25 #M4853 80 track drive
to work with my ST.

I had problems with the select lead not selecting the drive
but I was able to buffer it and get the ST to find the drive
on power up. But know it will not format. There seems to
be a problem with stepping the head. The Mitsubishi drive
has a 3ms step rate and should work with the ST. Also
the drive does work on another (non ST) system.

Do any other lead(s) need to be buffered ?

Summary: Current 520ST retail price?

Now that the 1020ST is coming out at a retail price of $999, will the 520ST still be available, will it have a new price, and if so what will that new price be?
Peter Espen

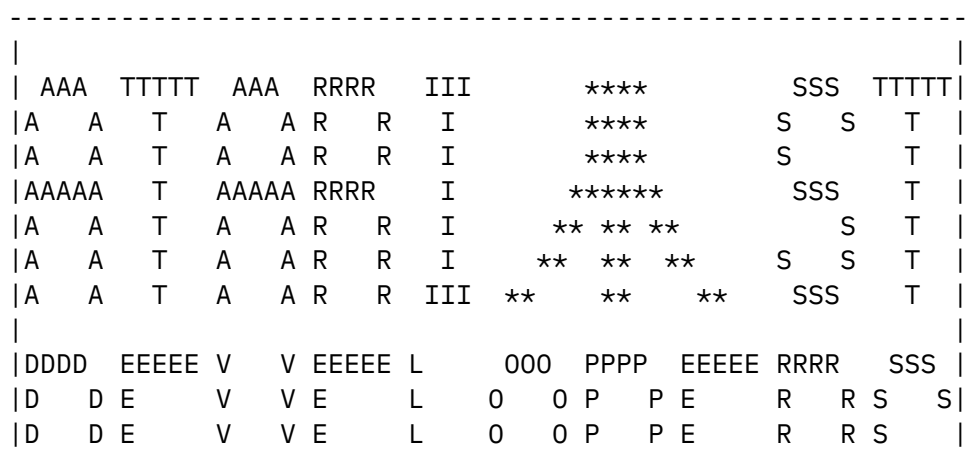
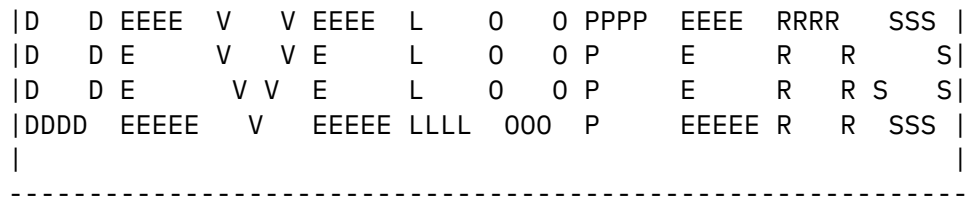
"Most Asked Questions #2"

This was posted on COMPUSERVE, and it is being re-posted on Usenet:





Question and Answer Bulletin March 1986
Copyright (C) 1986 by Atari Corp. "all rights reserved"
1196 Borregas Ave., Sunnyvale, Ca. 94086

Here are the latest questions from the Atari developers mailbag as answered by John Feagans, Director of Software Technology. Leave questions on Compuserve for PIN 70007,1072 or GO PCS57 for Atari developer SIG information.

How can I print the special characters in the Atari character set between codes 0 and 31?

You can use either the bios or the VDI. Device 5 on Bconout is a raw character output device that does not do an interpretation of character codes. You can alternate between output to console and this device to do cursor positioning and new lines. The VDI call to use is v_gtext. This routine accepts character indices between 0 and 255. You should be careful in using these character codes because they are only defined in the three system fonts: 6 x 6, 8 x 8, and 8 x 16. The VDI specification does not require loadable fonts to have characters in these positions.

When I dump a file to my printer, the first line prints across and then printing hangs up at the right margin. What is going on?

Check if your printer has a switch select position for generating a line feed after a carriage return is received. Some software will generate only a return and count on the Bios to generate the line-feed--TOS does not do this. If your printer does not have this facility, some programs such as STWriter and 1st Word have configuration files which define the end of line sequence which you can set for proper operation with your printer.

Why don't the numeric pad and the cursor keys work in the VT 52 emulator?

The layout of the ST keyboard is patterned after the DEC VT 220. The VT 52 is an older but still popular terminal and there is a dramatic difference--there are no cursor keys or a numeric pad. The VT-52 emulator is a faithful reproduction of this terminal--it does not use the cursor keys or the numeric pad. Here is a brief summary of cursor escapes. The full list is contained in the Hitchhiker's Guide.

ESC A	Cursor up
ESC B	Cursor down
ESC C	Cursor forward
ESC D	Cursor backward

I am writing a terminal emulator program. How can I smooth scroll the screen?

Refer to section 6 of the VDI manual on raster operations. You can use the copy raster functions, vro_cpyfm and vrt_cpyfm, to move blocks of data on the screen. You may also want to double buffer the screen. Furthermore you can move the pointer to the start of display memory.

My C program compiles fine but I get the following undefined symbols in the link68 step -- getscanf, printf, fpmult, and iob. I am linking with GEMLIB and LIBF.

There is no symbol getscanf. Perhaps you mean getchar and scanf? To resolve the other undefined symbols you must be sure to #include stdio.h and also be sure the start file you link with is gemstart.o

How can I write boot sector information? Is there an entry in the DOS or BIOS for doing this?

Use the protobt() extended BIOS call to create a boot sector. The disktype parameter should be 2 or 3 for 1 or 2 sided media respectively. The serialno parameter should be a random number. The execflag should be zero unless the prototyping buffer contains code (such as a copy of the loader) that you want executed when the disk is booted. Write the boot sector protyped in the buffer to track 0, side 0, sector 1 of the new disk. Use the extended bios function flopwr().

I am using funtion 7 of line-A. I am trying to use a pattern but I don't know what to put in the variable pattern_mask. pattern_address seems to be set up correctly because my pattern seems to almost come through.

The pattern_mask variable is actually the length of the pattern. That should be what will make your pattern work.

Question and Answer Bulletin

How can I put an icon on the desktop?

There is no way to place an icon other than those built into the system onto the desktop. The desktop is an application program and it was not designed to interface the other way from GEM AES. If you write your own application and create a new desktop, there is nothing to prevent you from using your own icons. A good example of this is the Resource Construction Set. If you want to represent a desk accessory by an icon you could open a nearly invisible window and print the icon on it. The limitation on this method would be that you could not drag other icons to it and be able to tell what was moved. If you want to be able to drag things to your program you must use the system icons. The procedure is to build a loadable driver and change the desktop.inf to contain the proper label information.

In the resource construction set, what is the difference between a free-tree and a dialog box?

A dialog box is a fixed format object list whose net result when you draw it is obviously--a dialog box. Its format is designed to work with the form library. The free tree is used to define other object lists. Of course you could define a structure for a dialog box with it--but you could also define a dialog box that had a different border and worked with your own form handler.

P_exec has two parameters which the documentation does make clear. They are the pointer to an environment string and a pointer to a command tail. What are these strings and how do I construct them?

The command tail is an array of strings terminated by a zero. If you do not use it then point to two consecutive zeros. The command tail is used by the run application dialog box for a TTP application. What you type in is inserted in the command tail. The environment string is something that is inherited by a process. It is just a simple string.

How can I display two dialog boxes at the same time?

The form library routines are designed for handling only one dialog box at a time. If you want to simultaneously display two of them then you will have to write your own form handler. They can be displayed using the object draw commands. You may also want to try form_button and form_keyboard which do not grab control of the screen. Look for documentation on these functions in this space soon.

My menus seem to have so many entries that they are of a certain size which prevents the AES from restoring what was under them when they pop back. What are the maximum size menus that I can have?

The total width times height in pixels cannot exceed 8k bytes for hi-res, 4k bytes for medioum res, and 2k bytes for low res. Assuming and 8 x 8 font or 8 bytes per character, a maximum for low res might be 256 characters--16 entries of 16 characters each.

What is the mechanism by which ST Writer reads the directory and prints the file names?

STWriter uses the F_sfirst and F_snext to read the directory entries. Furthermore, it uses some special data at the beginning of each file to indicate that it is an STWriter file.

How do I get the command tail from my C program?

TOS passes your program a count of parameters and a pointer to the array. Here is an example of how to declare them in your program:

```
main(argc,argv)
     int  argc;
     char *argv[];
     {
      /*    your program   */
     }
```

Are there any variables around so I can get the position of the cursor?

Since the orignal line-a variables offsets were frozen, we decided to expand the list. At a negative offset from the line a address there are two variables. v_cur_cx is at -14 words and v_cur_cy is at -13 words.

How can I ring a bell without going through the trouble of do_sound?

Send a control-G to console output: Bconout(2,7).

How do I access the data in an editable field from a dialog box that was created by the Resource Construction Set?

When you create the dialog box, use the Name function to give both the tree and the object a name which you can use later. Have the RCS create a .h file for your resource and #include it in your program. Define a pointer of type OBJECT and use rsc_gaddr with this pointer and the label for your tree to get the address of the start of the object list for the dialog. Later, you can index [label of object].ob_spec to get the pointer to the tedinfo structure. Do one more indirection to get the pointer to the actual string.

In article <648@anasazi.UUCP> john@anasazi.UUCP (John Moore) writes:
>I have heard that you can upgrade a 1040ST to 4 Meg by swapping the
>256K RAM's out and putting in 1 Meg RAM chips. Anyone know if this is true?
To answer my own question, it is true according to the interview in
Byte magazine, so I'll post another question:
     The upgrade of the 1040ST to 4 meg involves swapping the 256K RAM's
to 1 Meg. The 1 Megs have two more pins which the article said could
be bent out. DO they need to be connected to something (like more
address lines)?. Also, is there any reason this same trick cannot be
done with a 520 (using piggybacked 1 Meg chips)?

TITLE: First Look at Atari's IBM Box
microbytes/items #113 Thu Mar 13 14:44:36 1986

At the opening of the Hannover Fair in West Germany, Atari of Sunnyvale, CA, exhibited its IBM PC-compatibility box for the 520ST and 1040ST computers. While the product will not be ready for shipping until September at the earliest, its display to the public is thought to indicate that Atari is willing to go on record as backing this particular design. The box has its own 8088 built-in with a socket for the 8087. It also has 512K bytes of RAM. Connection to the Atari computer is via the DMA port.

With actual product introduction at least six to seven months away, Atari representatives would not discuss pricing beyond a statement that reaffirmed the company's history of producing "in high volume at low cost."

The announcement in Hannover reportedly does not signal an intention by the firm to earmark initial-release products for the European market in preference to North America. Company officials noted that this was simply the first public forum for which the unit was functional enough to be shown. Initially, Atari had planned to show the compatibility box last week in London but had to change its plans and move to Hannover when the unit proved not quite ready.

I thought these were good questions, the answers to which would be of
general interest.

1) All messages are in the archives. In addition, some contributed
programs are also there. The archives are in [SU-SCORE]<info-atari>.

2) The archives are stored in TOPS-20 message format (MM is the mail
handler used). After you have obtained a copy (see 3) below) your mailer
may be able to read these files. Probably not! I would suggest using
an editor to search for "Subject:" or whatever you are interested
in.

3) If you are on ARPANET or MILNET you can FTP from the archive. I don't
know how you can get the files otherwise. Any suggestions would be appreciated.
Te files are too big to mail; at least some mailers reject some of the files.
In general, the internet mail forwarders tend to reject very large files.
Also, and I don't mean to even appear unfriendly, the moderators just don't
have the time to respond to special requests. Be be honest, I sort of
regret volunteering to moderate this list. Even though I've gotten
help, it takes more time than I have and introduces a certain level of
frustration that I don't need. I'm not quiting (yet), but I don't see
any way to help you if you can't FTP.

Subject: Archives

As I am new to this list, I am wondering if you can explain something to me.

1) Are all the messages that come across the net in the Archives?
2) How do I find out what the subjects of these are so I can determine if I want to read any of them?
3) How to I get the messages/programs from the archieves when I have determined which I want?

Thank you for you time.

Jim Berg

In article <2018@uwmacc.UUCP> you write:
>*** REPLACE THIS LINE WITH YOUR MUSHROOMS ***
> Well, I don't (yet!) have my ST, but I want to be able to plug it in and
>start programming immediately (1/2 :-), so I'm going to be ordering software
>soon. Here's a very short summary of what I've seen here so far on the
>subject of languages:
>
>TDI Modula-2: Exciting, but has a bizarre object file format
>
>OSS Personal Pascal: Great! Impressive! Nifty!
>

  I don't want anyone to get the wrong impression; but I have been in the process of writing a multi-screen Tek 4010 emulator for the ST in OSS. Generaly, I am pleased with it but I have a few critical comments of the language, maybe someone can tell me (us) why these limits exist :

1) Arrays are limited to occupy less than 32K. Why is this? I thought that the 68000 had a continuous address space? I could very well be totally off base; but this is a minor problem as I can save the Tek screens in different arrays rather than the more elegent scheme of a multi-dimensional array.

2) Procedures (and I assume functions as well) are limited to 32K. Again, Why? This is a problem for me only when a single large procedure makes logical sense, and I have taken to writing in smaller chunks to get around this.

3) You can (on a 512K machine) compile up to a limit where the compiler generates an error something like 'Stack run into Heap', though it is documented in the manual this still puts an upper limit on the size of compiled modules to be linked later. This is OSS's suggestion: Chop your big program into smaller pieces and then compile seperately and link back together. I have personally found this limit on compile size to be about 1200 lines.

4) This is coupled to the previous one - The Linker will only allow you to link three user *.o files together. This with the limit above sets a limit to the size of program you can write on a 512K TOS on disk (standard) machine. This limit I have found to be *about* 3600 lines. This limit I have hit and now have to put TOS in ROM and get a 1Meg upgrade to finish the programming. I don't expect the terminal emulator to need more than the standard machine to run; but to get the program developed it takes quite a bit more.

5) This final item concerns an out and out error in the compiler and/or manual. The code is as follows:

```
var
  file_name : Path_Name;      { this is the file name I will use }
  Data_File : File of integer;  { This is the file type }
  i : integer;
  ...

begin
  ...
  file_name:='stuff.dat';
  Reset( Data_File, file_name );    { ready the file for reading }
  read( Data_File, i );        { read an integer }
                ^
               'Error in Standard procedure parameter'
```

The error is generated by the compiler. The manual shows this as a valid use of the procedures, but it will not compile. I have found (also from the manual) that Get() will do the job; but it is not a very 'clean' solution to the problem. The error also occurs when you use Rewrite() and write() together.

In general, for every problem there is a workable solution, but it would have been nice to not have to fight the compiler/linker to get a

big project through.
  To be fair, I still consider the OSS system to be a good buy, and a good system to develop in; but I don't want others to get stumped or surprised by finding what I have found.
  Please don't flame, I am just trying to help out with some lessons I have found out at the school of hard knocks.

          Bob

I have posted a very useful sector editor (in binary) to net.sources. It is only UUENCODED (not squeezed). Below is the documentation.

franco@indiana

THE NO-FRILLS ST SECTOR EDITOR v1.01

30 November 1985
James M. Eli
74176,2137

No-Frills Documentation:
     The author takes no responsiblity as to the quality or performance of this software. Use this at your own risk... preferably on backup copies. You can easily render programs, or entire disks useless, believe me I know!
     To Run: First set your screen resolution to MEDIUM, then simply double click on the program name. The title screen will prompt to insert your working disk and press RETURN (remember: use backups). The program will now initialize and read sector '0' of drive 'A'. From here on the program will

accept input in both upper and lower case. Use only the commands which are displayed, as there is limited error checking. Here is a breif description of the commands available:

O Toggles between the lower and upper halves of the 512 byte sector. Each time it displays 256 bytes (1-256/257-512) in both hexadecimal and ASCII format.

N New sector number to read or write. Be careful not to outstep the bounds of single (0-719) or double (0-1439) density drives. The noise this makes is enough to keep you from trying this more than once. If a sector less than 0 is requested, on the next read operation sector 0 is substituted.

R Read current sector.

W Write to current sector. You are given one chance to bail-out before you make a permanent change. Before going through with this operation check the drive & sector #'s, and be sure this is what you want.

+/- Respectively inrements or decrements the sector number, and then reads this sector. Should (!?) not step out-of-bounds.

M Modify data. Enter the location (1-512, making sure you are displaying the correct half), followed by the new byte. If a new location is not specified, consectutive bytes are accessed. Just hit RETURN when finished. Be careful now!

D Drive swap. Toggle between drive A and B.

P Prints the current sector in the buffer in both hex & ASCII. Dumps the data out the parallel port.

B Changes the background color (Did I say no frills?).

Q Quit and exit back to the Desktop.

The Read and Write status returned will be '0' for successful operations. Occasionally '-1' will pop up (which means: 'Anti-Success'), just check to make sure you requested a legal sector, your media is not write protected, etc. and try again. If everything checks out you probably found a bad or missing sector (intentional or otherwise). If you have used any of the sector editors for the 8-bit line you'll have no trouble here.

This program started out in Haba HIPPO-C, but was finished in the Alcyon C supplied with the developer's kit. HIPPO-C has a good programming environment which makes going from the editor to compiler to linker easy. Unfortunately HIPPO-C lacks the support in their library to make extended BIOS calls, this was the main reason to change C's. If there is enough interest in this out there, I'll consider enhancements (add drop-down menus and all that good GEM stuff), and possible future 'No-Frills' programs... how does a 'No-Frills ST Custom Formatter' sound?

>or is new hardware required?

The answer is New Hardware. What limits the resolution on the ST is the
amount of video memory (currently 32K). You would need to increase that
to get more resolution.

>When is the PC industry gonna "Grow up" and adopt even minimal standards?
>Does IBM have to do everything??!!!

Don't praise IBM. They have not produced "state of the art" personal
computers yet. What they have come out with is a family of horrible
personal computers for abominable prices. Maybe their new RISC machine
will finally be a good product, but that is not an attempt to establish
standards.

    We thought of that when we did the port of microEmacs here.
(that was posted to the net a while ago). The problem is that Vdi
text (v_gtext) is soooo slloooow. For the same reason a window (Vdi/Aes)based
browser would not be very useful.

    Almost all the rc_XX routine I have seen were written by Tim
Oren and are fully described in his Professional GEM seminar series
on Antic online. Another place to see the rc_XX routines are in the
Doodle source (which is where they originate from, also writen by Tim
Oren). I highly recommend the Professional Gem series and the
associated sources. If there is enough interest I can post them
(I have parts 1-10 and the associated sources), but i guess most
people have downloaded them by now.

Conversion of RGB to Composite signal can be done with a small amount of circuitry. I think there are IC chips that do most of the work. You have to construct luminance and chroma signals, which is just matrixing with resistors, and then modulate the chroma signal on a 3.57945-MHz color subcarrier and add it to the luminance to get the composite. Or something like that. (I can get exact details for you if you wish.)

I am planning to start an INFO-XLISP mailing list. The reasons for this are:

* To exchange XLISP code and ideas
* To provide an easy method of reporting bugs
* To facilitate the distribution of XLISP revisions (few people are aware that there is an XLISP 1.6 already and 1.7 is near completion)
* To collect enhancements to XLISP and collect the changes necessary to port XLISP to new machines

If you are interested in joining the list, please send mail to me at one of the addresses below. I will need your name and net address. I would also appreciate knowing what machine you use to run XLISP. I will then keep you informed about the INFO-XLISP details (such as the address) as they become final.

Dan

I know that it has been discussed a lot but because I just recently
got a 1040 and because I want to know what the *best* way is, could
someone fill me in on the following:

1) The best way to get software from a SysV unisoft machine to
   a ST
2) The best terminal emulator program (price *is* an object)

I have the developers kit on order. I do not have kermit on the Unix box.
I do not have xmodem on the Unix box. I am interested in the cheap and
easy way to get all the software I have stored from the net on to my new
toy. Thanks in advance.

Re the posting of the command description of UUENCODE/UUDECODE in reply
to the request (by Stephen Leicht) about the information.

I would assume that the question was for information of a more technical
nature, i.e. how is the file encoded? The command description does noone
any good unless they have the command on their system, in which case there
SHOULD be a decent on-line manual entry which describes the invocation.

Does anyone have a nice, concise description of the UUENCODE/UUDECODE
process? If it is too long to post to the net, could someone at least
send it directly to me?

In regards to John Sangster's posting about the simple circuit to convert
RGB signals to composite I would like to thank him for the information.

However I believe that the original request was about converting from
a composite signal to RGB, to enable the Atari monitor to be used with
a VCR. Does anyone have this information as well>

The 520ST is still available at $799 bundled with drive and monochrome
monitor, or $399 unbundled. The 520ST now includes an Rf modulator and
composite video output.

I have recently been in touch with the author of the "PDFORTH" that I posted to the net. I hope that at least most of you got that OK (I am frustrated by the fact that so much of what gets sent on the net winds up as garbage on the other end - at least I know the "PDFORTH" left here ok since I pulled it off the net and got it to work). Anyway, I thought you might be interested to know that what I sent out was a preliminary version of a FORTH that will eventually be marketed by a (one-man?) operation called Bradley Forthware. I have given the address below for anyone interested.

Also, I thought I would post part of our conversation which presents some of Mr. Bradley's thoughts on his FORTH. Please note that I am posting the information below only because some of you are porbably interested in the info provided. I am in no way endorsing this product. For all I know the info could be totally wrong. I have never met Mr. Bradley nor do I know anything about him except that he claims to have authored the "PDFORTH" (which, I suppose, should be relabeled BFORTH). Mr. Bradley does not know that I am posting the text of part of our conversation. The sentences preceeded by > are mine, the rest are his.

franco@indiana.CSNET

The address is:

Bradley Forthware
295 Hans Ave.
Mountain View CA 94040

> By the way - it works with TOS in ROM (at least on my machine).

I got around to trying out the version you posted after I sent you the message. I couldn't get it to work at all, but I found out enough to figure out why it works with the ROMs. The version you have copies itself to a fixed location in memory, which is about 0x50000 as I recall. This works okay but it fragments memory and doesn't give

you the full benefit of the memory that is available.

(note: The above applies only to the version I posted)

> By the way, from some crude benchmarks I
> ran it seems that your FORTH is at least as fast as DRAGON FORTH.

My analysis shows that my Forth is faster than Dragon Forth without
the accelerators, and slower than Dragon Forth with the accelerators.
The difference is due to my use of direct threaded code versus the
the indirect threaded code used by Dragon Forth. Direct threaded code
eliminates a memory fetch from the NEXT routine, so that NEXT becomes
2 instructions assembled in-line -- specifically

```
    MOVE.L  (A5)+,A0
    JMP  (A0)
```

I believe that this is the best that can be done with the 68000, short
of compiling directly to machine code. On the 68000, Direct Threaded
Code is even faster then subroutine threaded code, which many people
erroneously believe is the fastest.

The Dragon Forth accelerators work by compiling sections of machine
code in-line, eliminating NEXT overhead entirely. I think that Dragon
Forth is a very good system. The multitasking especially is very
complete.

Composite to RGB is similarly easy. Chips exist that do most of the work.
The National Semiconductor LM1828 an LM1848 for example (called "Chroma
Demodulators") take a composite or chroma input signal and give you "color
difference signals" out at 3 pins. Then you need to form three well-defined
linear combinations of these outputs, which requires hardly more than a
resistor network, to get RGB outputs. You will also need a Phase-Locked Loop

circuit to recover the color subcarrier and maybe some amplifier circuits to set levels and impedances, but the whole thing should be just a few chips.

There may be more sophisticated chips than the LM1828 and 1848 available as these were 1980-vintage stuff.

Incidentally, a tidbit of info from my video-expert cousin: if you are AC coupling composite or luminance video signals (as I plan to to in making my TV set into a monochrome monitor), use BIG FAT capacitors like 50 microFarads or you will get noticeable black level drift across the picture. The right way to do it is to DC couple, but you can get away with AC coupling if you use a big enough capacitor.

The chroma signal, being centered on 3.58 MHz, is less critical of low-frequency coupling and is shown in "typical application" diagrams for the LM1828 as being coupled through a .01 uFd capacitor into the 1K-ohm chroma input.

Hmm... I think this diagram is telling me that the correct mixing ratios (which would be reciprocals of resistor ratios going to the summing point) are as follows:

	LM1828	LM1848
R-Y	0.8	0.95
G-Y	0.25	0.35
B-Y	1.0	1.0

If anybody really wants to build converters for either direction, I could probably wheedle schematic diagrams out of my cousin, who is a fellow Atari owner and so should be sympathetic.

Browsing thru the 1980 National Semiconductor catalog, I find some other cute chips.

The LM1886 is a Video Matrix D-to-A Converter. This chip takes 3-bit inputs for Red, Green and Blue and produces luminance and color-difference outputs. The gadget can produce either NTSC ("Never Twice the Same Color") or PAL (European standard) outputs.

These analog outputs can be very easily turned into true RGB or Composite output, although you will need additional circuitry to come up with the sync pulses.

The LM1889 chip takes audio, color-difference and luminance signals and produces RF for your TV set antenna input terminals. (Or you can buy a whole TV modulator if you are lazy.)

Anybody interested in doing these kinds of things clearly should call up your nearest National rep and wheedle a Linear Data Book out of him. They are made to be given away if you ask nicely.

Signetics evidently has some good stuff too, including a new chip that my 1985 catalog doesn't list but which I think does NTSC to RGB decoding and has the

matrix built in. It is called the TDA3563, and is designed for use in TV receivers (all of which eventually have to produce RGB signals internally).

Related hint: If you own a color TV set of high quality, you should be able to add Composite and/or RGB inputs to it if you aren't afraid to tear it apart! Also you could modify it to do composite to RGB conversion but of course you might as well use its CRT display too in that case!

I have started to do some school work with 1st Word and it is working very nicely as a word processor (the price is right). I have run into some problems, however, that disturb me. After working some time on a document (with many incremental saves), I needed to look up a function in the 1st Word Guide. I loaded the Guide and did a FIND. What the find found was my document stuck right in the middle of the Guide. I rebooted and tried the same thing again and sure enough, my document was still part of the guide.

What is going on? Is 1st Word doing this or (horrors) is TOS doing this? I don't have TOS in ROM yet so I guess there is still hope if TOS is the culprit but it is very disconcerting not knowing when or what files will get zapped. Maybe Neil at Atari can help on this one.

BTW, before this happened I noted some instances of similar things happening with the Guide where parts of it were copied spuriously into other files so this seems to be an ongoing problem.

Help, before I buy a hard disk.

I don't understand this comment. There is nothing special about the video
memory. The bitmap is just part of memory, restricted by the refresh hardware
to start on a 512 byte boundary. What limits the video memory to 32k at
present is the addressing scheme in the refresh. It strikes me as being
arbitrary and I hope there are hidden capabilities in that refresh circuitry
to support higher res.

    There were rumors earlier to the effect of Atari
    (DRI??) rewritting the documentation for the
    developers kit, as well as improving the compiler,
    linker, assembler. Can anyone fill us in on the
    status of these??? Are they for real?? Should we
    wait for them or are they so far in the future
    that one shouldn't wait?? I desperately need the
    info, but don't want to spend my money on "bad"
    documention when there is any better to be had.
    (I have the Abacus dox's already, enough spent
      on unclear documentation...)

Thanx

***** Nobody knows the lines I've eaten - song title *****

It's about time I make another comment on the jolly black power supplies. A couple of days ago, my TOS ROM(s) blew. I deduced this from the fact that all went well with the old chips replaced. It took a week for the new chips to stop working. But I gather that these ROMs are really Eproms which happen to be opaque, which makes them somewhat vulnerable to the dreaded power supply surge.
   Now the people who told me about the power supply scandal have consequently informed me that a very simple test will determine whether the power supply is of the evil variety, without having to wait for disaster to visit. It seems that with zero load, a humble voltmeter will demonstrate the true nature of the thing. So this would indicate that the same fault that causes sub-optimal start-up characteristics also causes inappropriate response to zero load. If so, this would help prevent a lot of indecision about what to do with "the black power supplies".

***** The lines that ate Paris - film title *****

I've just been shopping around for world ST prices, and these are the results:

In Australia, the standard B/W system that costs some $700 or so here, costs A$2150 x .704 = US$1510. And the government only takes 20%. Someone is making a big profit over there! But then I suppose some sort of voltage conversion has to be made.

In Germany, the cost is DM2898 x .444 = US$1285 for the 1 Meg system with German keyboard and TOS on disk (still!), and the double sided disk drive. That's the 520ST+ that has been mentioned here before.

But in Germany now, it seems they have a 1040STS or something, with a built-in double-sided floppy for DM3298 x .444 = US1465. And these two are also just the B/W system.

The good news for anyone going to these exotic places is that according to the Atari person who answered the phone in CA, the American version will run on 50Hz with a transformer, but that the keyboard clock will run at 5/6 speed!!! Doesn't this suggest that some crucial part of the keyboard circuit can be replaced with a German part to make it run at the speed?

It's very clear to me now that the best policy is to buy here and use a transformer overseas.

Can anyone say whether STs have got beyond the US, Canada, UK, Germany Australia and Switzerland? The Bios listing suggests a French version, but that could conceivably have gone only to Quebec. Perhaps the English language component of TOS will be rejected by the Ministry of Culture. And what is this new French computer language coming out soon? I've seen a sample of French Basic. If anyone has a copy of French Basic for the ST I would gladly know about it.

.....ak.

I have received several requests for detailed information so I shall try to prevail on my cousin for schematics for the cases mentioned in these requests.

I will post an announcement here when they are available, and will probably also send them out to those who gave mailing addresses as I guess I can afford the present $1 or so of postage. If the list gets a lot longer, I will however request SASEs in the time-honored tradition.

Please allow 2 to 3 weeks for delivery...on this promise. Please feel free to remind me if you haven't heard from me by Tax Day or so.

Summary: Standards please!!!

In article <2807@reed.UUCP> rosalia@reed.UUCP (Mark Galassi) writes:
>>When is the PC industry gonna "Grow up" and adopt even minimal standards?
>>Does IBM have to do everything??!!!
>
>Don't praise IBM.
Who's praising IBM???

>Maybe their new RISC machine
>will finally be a good product, but that is not an attempt to establish
>standards.
I haven't heard much good about the RISC machine. Who cares, this is Atari group anyway right? :-).

What I am upset about is the appearant contempt for even minimal standards between Atari, Commodore, and Apple. This appears to be changing, Apple is putting SCSI on the Mac, Commodore is considering adopting NAPLPS as a file storage/transfer format. What is Atari doing???

The sooner some simple standards for peripherals, software, and data formats are adopted, the better. In most other Consumer Electronics industries, standards have made it possible for each company to capitalize on their particular strengths.

Atari makes some good computers, but on the 800 line, only Atari peripherals can be used. Even a "generic" modem required the 850 interface box.

To be fair, the main reason I like the Atari 520-ST is because they DID attempt to put some very good standards in their machine. DRI wrote the operating system (better than CP/M68K), they built in the RS-232 and Centronics (with adapter cable) interface, and used a well vectored OS rather than leaving people to go poking and jumping into strange ROM vectors. Good job Atari!!!:-)

What has me concerned is the "Upgrade Path" for this and future machines. Another concern is that I might get tied to Atari's trade-off choices. If Atari comes out with a fully supported SCSI interface, we'll have the choice of over 100 mass storage devices, including removable, winchester, and tape drives. Maybe the SCSI command set isn't complete enough to be truly generic yet?

I can't say I'm thrilled at the prospect of buying a 520 only to discover that the 1040 makes the 520 obsolete, or that the TT series will make the ST series obsolete. In the Byte interview the guy said that upgrading the 1040 to 4 meg would be "Trivial". Yes it will be trivial to add the extra two pins to the design and manufacture process, but don't expect to be able to simply plug in 1 meg chips and have 2 or 4 meg. Expect to have to buy a NEW MACHINE :-(. Don't expect software vendors to stick to 512K either, unless Atari starts making concurrency available, along with a real MMU, the applications will grow to fit the available memory. In other words, unless you upgrade, your 520 may be obsolete in another 6 months. According to some reports, the ST is really only the TERMINAL for their "Real" "Personal Mini" TT computer. Is that another $1000?

Notice the CPU is soldered in? Ever tried de-soldering a 64 pin chip? Notice the RAM is also soldered in? Notice there is no header for a Piggy-Back RAM board? I would hope that these were oversights rather than deliberate choices. All of these choices together might have added $100 to the purchase price. It would have been worth it considering the alternative is either a lot of manual "hot wiring" or buying a new computer every six months. Even adding a few address lines to the DMA ports would have helped.

I've said before, I like the Atari, but I'd like to make sure that "Cheap Computer" doesn't mean "Disposable Computer". What plans are in the works NOW that will keep this from happening? I would definately like to see a socket compatible MMU, and a 68010 upgrade path. Also, higher resolution (1024X1024?) if the 70HZ is to be

justified.

This attitude really bothers me. Why does one camp of computer user feel
that they have to put down another camp? Or feel that "our" computer is
better than "theirs?"

I own both an IBM XT (well, "portable," but close enough...same motherboard)
and an Atari 520ST. They are both nice computers...one can do some things the
other can't, and visa versa. (For example, the Atari has a faster processor and
obviously better graphics than the IBM, but I like the programming environment
in the IBM better than that of the Atari.)

When are computer users gonna "Grow up"?

The 1040ST, and now the 520ST, offer composite video output compatible with normal monitors, or rf-modulated for TVs. There were a few questions here a while back about how the ST reads its video memory to drive the display without slowing down the processor (answer--video reads are done while the processor isn't using the bus, mostly) but now Atari has come out with an additional video output, which can't be compatible with the "normal" display drive as that is 70Hz, non-interlaced and regular monitors are 60Hz, interlaced. Does the new 60Hz display use the same technique as before, using the bus alernately with the processor, so all three of them are banging away? This makes it seem like there would be frequent bus-contention, especially between the 60Hz and 70Hz accesses. Is there some kind of magic that makes this less of a problem?

I've solved this by converting files to standard ASCII (non-WP),
and then printing from the desktop, but this is a major bummer.

Also occasionally I find I can insert page breaks but can't get
rid of them by clicking the mouse on them. Has anyone else had
this problem?

Otherwise I love 1st Word. I think the method it uses to get
Greek letters and math symbols is the best I've come across.

I had a talk with my video expert cousin, John Hain, and learned some facts of interest to those contemplating conversion projects.

(NOTE: This is my first login from home on my Atari 800XL, so if anything looks strange please bear with me.)

The most important new information I gor(oops) got was that generating RGB from composite is doomed to lower resolution than a good RGB monitor is capable of providing. That's the bad news. The good news is that if the luminance and chroma signals
are available separately, then you can get darn near the full resolution of the best RGB monitor!

Even better, John and a friend of his in Huntsville, where he lives, are already at work building a real circuit to do just that--take the output of an 800 series Atari, which has chroma available separately, and make RGB. The first attempt was partially successful, but they think they will get more accurate color balance and better resolution with a different IC.

After my inquiry, John says he will get back to his friend to see where the project stands right now and see if he
can expedite completion of the final design. Probably a complete, TESTED design will result.

RGB to composite can apparently be made essentialy as good as the composite monitor can display anyway.

If somebody can start researching the availability of chroma and luminance signals separately in thwill know where we stand. Wait a minute...does the ST already put out RGB or composite? Obviously it is too late at night and I should get back to this
tomorrow!

Like the subject says, I'm looking for any decent (*not* Lattice) 68000 C cross-compiler, which would run on an IBM PC/AT running SCO's Xenix System V, and compile to CP/M-68K object format (to eventually run on an Atari ST).

So far I know that Manx (Aztec C) doesn't have anything ready, Greenhills C only runs on VAXen, and of course Megamax, Alcyon, and Hippo C are only native mode.

I believe that changing the height will work, by using something like
vst_height(handle, height, &dummy1, &dummy2, &dummy3, &dummy4)
with height=6. I've tried this with height=4 and you still get the
6x6 system font. I also would like a pointer to any font editors,
especially one which will work with TOS in ROM.

(* I posted this message last Sunday to INFO-ATARI instead of to *)
(* INFO-ATARI16. My apologies to those who must read it again.   *)

There are a number of bugs in the InOut module for TDI's Modula-2
compiler. I saw recently on info-atari that someone was having touble
reading integers from a disk file. Here's why:

Procedure Read does not convert CR-LF pairs to a single EOL character, but returns both characters individually.

Procedure ReadString does not stop reading when it finds a trailing space, but goes up to the next control character. Since ReadCard and ReadInt use ReadString, if you try to read several integers or cardinals from a single line, you will get a runtime error (#9) because a string with embedded blanks is not valid for conversion to those types.

Due to the bug in Read described above, ReadString will find a null string at the end of every line, sandwiched between the CR and LF.

Procedure Read sets the Done flag to FALSE one character too soon. Upon returning from Read after reading the last character in a file, I find that Done = FALSE. That should be so only after a Read call made AFTER the last character has been input. Done is a signal that Read HAS failed, not that it WILL fail.

Variable termCH is always set to 0C after a call to ReadString, ReadCard, or ReadInt. While it is true that 0C is used internally by TDI Modula-2 to terminate strings, termCH is supposed to be the character on the EXTERNAL medium that caused the procedure to stop reading, e.g., a space, a control character, or EOL.

Procedure Write, when called with EOL as the argument, just writes the one character. Therefore, Write(EOL) is not equivalent to WriteLn, which writes CR-LF.

The following, while not exactly bugs, I consider to be annoying mis-features:

Although the OpenInput and OpenOutput procedures take a string argument called defext, it is ignored. I think that the argument is allowed only for compatibility with other implementations of Modula-2, but the manual doesn't say that.

The screen is not placed in some standard state when a Modula-2 program starts. Therefore, where the first output appears depends upon where a previous program left off, which might be anywhere. I would like to have the screen cleared and the cursor homed automatically on start-up. There seems to be no simple way to do this myself without using VDI.

A null string "" is allowed as an argument to a procedure that has a VAR ARRAY OF CHAR formal parameter, as is a string with multiple characters. A one-character string constant is not, being considered as type CHAR. Apparently this is due to the fact that open array parameters must be declared VAR, that type CHAR is not compatible with ARRAY OF CHAR but only assignment

> compatible, and that the types of arguments given for VAR
> parameters must be compatible with the type of the formal.
> Whew! Isn't this taking strict typing too far?

I called the TDI offices in Dallas about the bugs, and will be sending them documentation sometime this week. I was told that it will probably be a couple of months before fixes are sent out, partly because all development work is done in England, partly because a new release of Modula-2 is planned for then anyway.

To tide me over until then, I am going to write a new implementation module for for InOut. I will gladly share it with anyone who wants it, but I would like to make it as "standard" as possible. There are a few details of the implementation that Wirth does not make clear in "Programming in Modula-2" (second edition).

> Under what circumstances should ReadString return a null
> string? From Wirth's description, it seems that it returns a
> null string at the end of every line that has more than one
> trailing blank. That would be a nuisance if you're trying to
> read a text file word by word.
>
> Shouldn't leading tabs be skipped by ReadString as well as
> leading blanks?
>
> What provision is to be made for signalling end-of-file for
> terminal input? A program that tests the Done flag should be
> able to read from a terminal as well as from a disk file.
>
> Assuming that ReadCard and ReadInt use ReadString, what should
> they do if they read a null string: return zero, cause a
> run-time error, or keep reading (with a prompt for terminal
> input)?

Let's have some discussion about this. After all, programs using InOut are supposed to be portable.

To all the hackers out there in ST land.

I am posting this in the hope that someone can provide me a few clues to the following questions:

1. Has anyone tried to get their own hard disc up and running on the ST either 520 (512 or upgrade to 1024 k) or 520+ (European 1040)?

2. What hard disc controller and also what make and size of hard disc did you use? Is there a limit to the hard disc size the ST can handle?

3. Does the ST operating system, TDOS, come with software support for the SCSI/ SASI hard disc bus built into the ST?

4. If there is no built in hard disc software support is there any mention in the developer's manuals of how to hook up and run a hard disc.

5. How does the Habba Hard Disc for the ST handle the software required to run the hard disc? Is there overlay or other software provided by Habba for TDOS or is TDOS smart enough to look at the hard disc port on cold boot? If so can you select to boot from the hard disc and does this provide autoexec software capabilities similar to that available on CP/M and PC machines?

6. What sort of hard disc controller do Habba use? Is it their own design or do they use a WD1000, Shugart 1610 or similar SCSI/SASI type controller?

7. In the November 1985 Antic magazine there is an article which shows you how to attach a 5 1/4" DSDD 40 or 80 track drive to the ST. Has anyone had a go at doing this yet? If so, were there any hassles either in the hardware or with the operation of the drive in the system? Are there any limitations to the use of this type of drive on the ST, ie. incompatability with the OS, sacrifice in file transfer speed, file transfer size limitations?. Could you use two 5 1/4" drives in place of the 3 1/2" drives if you have TDOS in ROM? I would prefer to have 700k odd capacity on discs that costs 1/3 of the 3 1/2" price.

If these questions have been asked and answered previously maybe someone could mail me a copy privately. If not, I am sure that there are others out there somewhere who would like to have a go at rolling their own hard disc and maybe adding a 5 1/4" DSDD disc drive as well.

For anyone interested in the 5 1/4" drives there are 96TPI (80 track) full height 5 1/4" drives available through mail order houses for about $US50 at

the moment. With a case, power supply and cables you can have drive up and running for well under $US100. Beats the ATARI price by quite a few bucks and if you need it (you might want to upgrade your PC, XT, AT to a real machine) you will have built-in 5 1/4" IBM disc reading capability for tranfering text files to your ST.

Thanks in advance for any help.

When redirecting input, i.e. foo <file
I get -1 when doing getw(stdin) or getl(stdin)
on code generated by the DRI C compiler. Does anyone know a way around the problem? Does anyone know if the problem occurs in the C compiler, in the COMMAND.TOS program, or elsewhere?

By the way, I have been quite happy with the DRI C compiler, except for issues relating to input and output.

Which RAM disk are you using? With the public domain RAM disk I am
using, things don't work after a few compiles. Removing all files
from the disk before each recompile seems to keep it going longer
but that is not convienent if you also put libraries on it.
(I tried to mail this, but my machine does not know how to reach you.)

Paul Purdom (purdom@indiana on CSnet).

I have a better idea. Let's admit to ourselves that the ST doesn't need
Electronic Arts products and we ST owners don't care for thier pompous
attitudes. Let's vote with our dollar by not buying any EA products.
If anyone is waiting for a really good game for the ST, wait no longer.
Go out and get a copy of SUNDOG. All of the ST owners I know
have purchased this game and we are all getting really addicted to it.
A lot of other really good ST software is coming, both games and
productivity. Megamax is here, I own a copy and it is a really
great compiler. A lot of software companies that were taking a "wait
and see" attitude are jumping on the bandwagon (Borland for one).
Believe me, ST owners won't be hurting, even if EA goes totally
down the tubes.

I've been faithfully calling Atari dealers for about 3 weeks now
trying to find a 1040ST. I get the same story every week -
Atari has delayed the shipment, but they're supposed to ship
NEXT week. So what's the scoop here - do 1040ST's really exist
or am I just being string along???

To all the hackers out there in ST land.

I am posting this in the hope that someone can provide me a few clues to the following questions:

1. Has anyone tried to get their own hard disc up and running on the ST either 520 (512 or upgrade to 1024 k) or 520+ (European 1040)?

2. What hard disc controller and also what make and size of hard disc did you use? Is there a limit to the hard disc size the ST can handle?

3. Does the ST operating system, TDOS, come with software support for the SCSI/ SASI hard disc bus built into the ST?

4. If there is no built in hard disc software support is there any mention in the developer's manuals of how to hook up and run a hard disc.

5. How does the Habba Hard Disc for the ST handle the software required to run the hard disc? Is there overlay or other software provided by Habba for TDOS or is TDOS smart enough to look at the hard disc port on cold boot? If so can you select to boot from the hard disc and does this provide autoexec software capabilities similar to that available on CP/M and PC machines?

6. What sort of hard disc controller do Habba use? Is it their own design or do they use a WD1000, Shugart 1610 or similar SCSI/SASI type controller?

7. In the November 1985 Antic magazine there is an article which shows you how to attach a 5 1/4" DSDD 40 or 80 track drive to the ST. Has anyone had a go at doing this yet? If so, were there any hassles either in the hardware or with the operation of the drive in the system? Are there any limitations to the use of this type of drive on the ST, ie. incompatability with the OS, sacrifice in file transfer speed, file transfer size limitations?. Could you

use two 5 1/4" drives in place of the 3 1/2" drives if you have TDOS in ROM? I would prefer to have 700k odd capacity on discs that costs 1/3 of the 3 1/2" price.

If these questions have been asked and answered previously maybe someone could mail me a copy privately. If not, I am sure that there are others out there somewhere who would like to have a go at rolling their own hard disc and maybe adding a 5 1/4" DSDD disc drive as well.

For anyone interested in the 5 1/4" drives there are 96TPI (80 track) full height 5 1/4" drives available through mail order houses for about $US50 at the moment. With a case, power supply and cables you can have drive up and running for well under $US100. Beats the ATARI price by quite a few bucks and if you need it (you might want to upgrade your PC, XT, AT to a real machine) you will have built-in 5 1/4" IBM disc reading capability for tranfering text files to your ST.

Thanks in advance for any help.

The following is a little program I wrote to transfer files from a TOS disk to a CP/M disk. It works all right in test, but when I run it on the ST all the block numbers are off by one. Kludging the program to increment the block number doesn't seem to work. Could someone tell me the format used for the CP/M disks? The "#define"s show the values I've used, and they seem to work mostly, except that the files all begin one block farther along then I think they should.

The program follows.

```
/*****************************************************************************
*    STXFER.C
*
*    Compile with Alcyon C, using the CLIB supplied with the ST Developers
*    Kit.
*
*    Program to transfer files from a TOS formatted diskette to a CP/M
*    formatted disk. CP/M formatted disks are the same as TOS disks, but
*    they have no TOS files, or even a volume label, on them.
*
*    This program is my own creation, and has absolutely nothing to do with
*    Digital Research, Inc., or Atari, and should not be construed as
*    being any part nor portion of any product, announced or no, from either
*    of these two companies.
*
*    This is released to the public domain, and shouldn't be sold or any
*    of that. I reserve the copyright, and the right to change it, or
*    fix it, etc.
*
*    Copyright (c) 1986, Bruce Holloway
*****************************************************************************/

awhile ago there was an article on connecting IBM PC 5 1/4" drives
to the ST, does anyone remember where the article was published ?
```

has anyone tried it ? any horror stories ?

Use vst_point and set the point size to 1. It will use the next larger font,
which will be the 6x6 font you need.

5,25 floppies with 80 tracks (SSor DS) are working properly.

But some caution should be done before connecting them.

1. Drive select should be buffered with a 7407.

   otherwise older drives can overload the sound chip.

2. Remove any pull up R's in the floppy

3. Open floppy 1 and connect your extension cable to the Shugard bus.

***Don't forget the drive select. (from OUT)

CURRENT STATE OF THE LIBRARY

This is a followup of my message on Feb. 9. Sorry it took me so long to get organized. I thank everyone who sent me encouraging messages, suggestions, and offers to assist. I have thus far sorted thru approx 600 files, took what I thought would be of most interest to the serious ST user, and compiled a set of 8 single-sided/4 double-sided disks. More disks are on their way. If you don't yet have a library, or are trying to get a user group started, I will distribute disks in our library on either single- or double-sided disks. The charge for a single-sided disk is $6 in which case you can select the disks you want individually. I am posting the directory listing of each single-sided disk on this bulletin bboard in groups of two. If you want double-sided diskettes, please order the pair of disks listed on one of my announcements together (in order to simplify my copying procedure) as one double-sided diskette for $10. I will ship 1st class domestic, so if you are overseas or desire special shipping, please add the appropriate amount.

There is plenty of public domain software, but acquiring, testing, and documenting each piece (I have learned!) is extremely time-consuming. So I ask for others' help: if you are liason to a user group or have written software yourself for the public domain, I will be happy to trade with you disks on a one-for-one basis, which would augment both our libraries. Just drop me a note and we'll compare lists for overlap.

So here are the first two disks:

ST Public Domain Software Library

****** DISK #1 -- MISC UTILITIES ******

READ_ME The contents of this disk (what you are reading).

ACCS (folder) A collection of desk accessories.

  FREERAM.ACC Displays no. of bytes unused (available to application).

  RAMD97K.DOC Instructions for using ramdisk below.

  RAMD97K.ACC Creates 97kbyte ramdisk at system boot. Must install (and can save using SAVE DESKTOP) drive "D".

  RAMDISK.ACC Creates ramdisk and loads entire contents of disk onto ramdisk. Must install pseudo disk drive "D", which will then be the ramdisk.

SAMPLE.ACC	Sample desk accessory which when selected creates full-screen resizable ellipse filled with Atari logo.
SPOOL.ACC	Printing spooler.

BTERM.C	C source for dumb-terminal emulator uses procedures defined in BXFER.C.
BXFER.C	C source for Lattice C which implements file transfer using CompuServe "B" protocol. Untested.
CALC.PRG	Simple, four-function calculator.
COMPARE.PAS	Pascal program to check for equality of two files.
COMPARE.PRG	Compiled version of above.
DEBUG.C	Utility C code which provides "printf-like" procedures for use in debugging in GEM.
DEG2NEO.TTP	Degas to Neochrome format picture converter.
DISKDOC.PRG	VERY useful utility from Antic to inspect and repair disks. Data may be viewed by file or by sector. This program makes full use of GEM features; I was suprised to see a program so polished in the public domain.
DSBOOT.PRG	Makes double-sided disks bootable.
DUMP.DOC	Instructions for program below.
DUMP.TOS	Provides hexadecimal/ASCII dump of file.
EFFCTNEO.PRG	Displays Neochrome (.NEO) files using various special effects.
FILECOPY.PRG	Program to read files into temporary storage then dump them from memory onto (presumably) other disks to make backups.
FIXREAL.PAS	Utility Pascal procedure which rounds real numbers to specifed precision.
FONT.C	Program to convert fonts from 8-bit Ataris to Degas format.
FONT.PRG	Compiled version of above.
FORMATED.PRG	Atari disk format utility which includes setting as executable the boot sector, and defining a serial number in the boot sector. Untested.

HI25.PRG	Program for monochrome systems which adjusts the height of the characters to yield 25 lines of text on the screen.
HI25.S	Assembler source for above.
HI50.PRG	Like HI25.PRG except that the characters' height is adjusted so that 50 lines will fit on the screen.
HI50.S	Assembler source for above.
ICON8.DOC	Instructions for following program.
ICON8.TOS	Icon editor which displays and allows editing of eight icons simultaneously.
KOA2DEG.PRG	Koala to Degas format picture converter.
LISTFILE.PAS	Pascal program to dump source code to a printer, with consideration given to page width and length.
LISTFILE.TOS	Compiled version of above.
MAKE1MEG.TOS	Adjusts values of memory parameters so that machine believes 1 meg of memory is available. (They would normally be set automatically at boot time.) This effect is the opposite of that caused by the following program.
MAKE512K.TOS	Convinces machine that only 512K of memory is available.
MUSH.TOS	Provides interpretation, register dump, and partial stack dump of program state which caused crash. Useful for debugging.
NEO2DEG.PRG	Neochrome to Degas format picture converter.
NOVERIFY.PRG	Cancels the read-after-write verification which normally occurs when writing to disk.
PRINTDIR.DOC	Instructions for program below.
PRINTDIR.PRG	Program to print recursively the directory structure of an entire disk.
PRINTDIR.RSC	Resource file for above.
RAMCOPY.FIL	Text file which contains list of programs to be copied into ramdisk when the following program is executed. Useful, for instance, when collecting various frequently-used utilities in the ramdisk.
RAMCOPY.PRG	Program to copy files listed in RAMCOPY.FIL into ramdisk (device H:).

SECED.DOC Instructions for program below.

SECED.PRG Editor for disk sectors. Useful for inspecting and restoring damaged disks. Hexadecimal and ASCII values are displayed.

SETTIME.TOS Program to query the user for time and date and set the system clock accordingly.

SLIDENEO.PRG Displays all Neochrome pictures in the current directory in succession, creating a slide show.

SLIDEDEG.PRG As above, except for Degas picture files.

SLIDEPIC.PRG As above, except for .PIC (old Neochrome) picture files.

SQUSQ.DOC Instructions for using STSQ.TTP and STUSQ.TTP below.

STSQ.TTP "ST SQueeze": utility to compress binary or text files.

STUSQ.TTP "ST UnSQueeze": the inverse of STSQ.TTP above.

TIMESET.PAS Pascal source for another program to set the system clock.

TIMESET.PRG Compiled version of above.

VARRECS.PAS Type declarations of variant records which can be used to coerce types (i.e., circumvent type-checking).

VERIFY.PRG Cancels the effect of NOVERIFY.PRG. Read-after-write verification resumes when writing to disk.

****** DISK #2 -- DEMOS ******

READ_ME Contents of disk (what you are reading).

BOINK.PRG Bouncing, rotating checkered sphere complete with sound effects; Atari's answer to Amiga demo.

CHESS.PRG Impressive demo of forthcoming 3-D chess game.

CIRCLES.PRG Balls bounce in confines of rectangle with rectangular grid superimposed.

COLOR512.PRG Displays all 512 color simultaneously; RGB components of each color is displayed when pointed to by mouse. Use color monitor in low-res mode. Space bar quits demo.

CORES.PRG Hexagons form colored columns; bad termination sometimes requires reboot.

COSINE.PRG Colored lines form overlapping waves.

CUBE.PRG	3-D rotating cube; space bar quits demo.
HEX.PRG	Colored hexagons spiral to form larger hexagons; bad termination sometimes requires reboot.
KALEIDSC.PRG	Octagonal kaleidoscope.
MANDBROT.PRG	Program to request parameters of, then plot fractal.
MANDELBR.DOC	Explanation of program below.
MANDELBR.PRG	Displays Mandelbrot fractal, and allows region selected by mouse for "zoom-in".
PIECHART.PRG	Sample multi-color piechart.
PIESLICE.PRG	A cylinder is drawn then slices move in and out.
PROFESS.PRG	Demo of VIP-Professional shows layout of spreadsheet.
PROFESS.RSC	Resource file for above.
QAX.PRG	More lines moving around the screen.
QUIX.PRG	Monochrome lines bounce off screen borders (as in arcade game of same name).
QUX.PRG	Collections of moving parallel lines provide illusion of transforming 3-D image.
RTXDEMO.C	C program executed in demo below.
RTXDEMO.PRG	Demo of multitasking OS kernel being developed for ST.
SIEVE.PRG	Sieve of Eratosthenes benchmark for Personal Pascal.
SPARKLER.DOC	Instructions for below.
SPARKLER.PRG	Electronic version of firework.
STARDEMO.PIC	Picture file for program below.
STARDEMO.PRG	Teaser for forthcoming game.
ZAPLINES.C	Demonstrates graphics, sound effects from C.
ZAPLINES.DOC	Instructions for program ZAPLINES.
ZAPLINES.PRG	Compiled version of above.

ST Public Domain Software Library

****** DISK #3 -- BASIC Programs, Misc Resources ******

READ_ME   The contents of this disk (what you are reading).

1STWORD.PRT   (folder) Contains configurations of common printers for
                use with the 1st Word word processor:

  ASCII.HEX   QUME.HEX
  CITOH.HEX   SG10.HEX
  EPS_RX80.HEX   SMM804.HEX
  OLYMPIAN.HEX   TOSHIBA.HEX
  OLYMPIAR.HEX   GEMINI10.HEX

BASIC   (folder) A variety of BASIC programs.

123RANGE.BAS	Program to list the Lotus Range Names used in a spreadsheet file.
BACKGAMN.BAS	The game of backgammon.
CHECK.BAS	Checkbook program for the ST which allows accomodates printing of checks and reports.
CHECK.DOC	Instructions for using above program.
CHECKER.BAS	The use of peeks and pokes to find screen dimensions is demonstrated.
CHIMES.BAS	Sound demo.
FINPAK.BAS	Financial package calculates interest, depreciation, loan schedules, future value.
JOURNE.BAS	Verbal adventure game.
MIDIPLAY.BAS	Sample BASIC program which interacts with midi port.
MOUSE.BAS	Demonstration of accessing the mouse registers in BASIC.
SILENT.BAS	Demo of use of Midi in BASIC (plays "Silent Night").
STMASTER.BAS	The game of Mastermind. Very nicely done.
WAVE.DOC	Tips on using the BASIC Wave function.

DEGAS.PRT (folder) Contains configurations of common printers for use with the Degas program.

EPSON.PRT	JX80C.PRT
EPSON2.PRT	MLN193.PRT
EPSON3.PRT	OKI20B.PRT
IBMPRO.PRT	OKI20C.PRT

FONTS (folder) A collection of fonts.

ADVENTUR.FNT	DAVESNEW.FNT	SCRIPT.FNT
ARCHAILF.FNT	FANCY.FNT	SERIF.FNT
BIGM.FNT	GOTHIC.FNT	SHADOW.FNT
BLOCK.FNT	HEX.FNT	SQUARE.FNT
BOZO.FNT	IBM.FNT	SQUATTY.FNT
COMP.FNT	ITALIC.FNT	STANDARD.FNT
COMPUTER.FNT	MODERN.FNT	STANDRD2.FNT
COMPUTR2.FNT	NEWCOMP.FNT	STYLISH.FNT
CURSIVE.FNT	OLDSTYLE.FNT	SYSTEM.FNT
CURSIVE2.FNT	OUTLINE.FNT	TECHNICL.FNT

DAVES.FNT ROMAN.FNT UNDERLIN.FNT

CLOCK.ICN Sample icon of an analog clock.

CLOCKM.ICN Mask for above icon.

IBMPRO.DOC Configuration tables for IBM Pro-Printer.

****** DISK #4 -- Utilities ******

READ_ME The contents of this disk (what you are reading).

ACCS (folder) More desk accessories.

BREAKOUT.ACC Miniature version of arcade game.

CALENDAR.ACC Shows monthly calendars thru Dec, 2009. Vertical scroll selects year, month.

CLOCK.ACC Analog clock. Variable length, width.

CONTROL.ACC Usual control panel to customize colors, keyboard parms, and set time.

HEXCALC.ACC Decimal, hexadecimal calculator for monochrome system.

HEXCALC.DOC Instructions for using above desk accessory.

PUZZLE.ACC Mac-like puzzle of sliding tiles.

VT52.ACC VT52 terminal emulator.

WATCH.ACC Digital watch and date. Display is undated even when watch window is not selected.

DBMASTER (folder) Programs for DBMaster database program.

MAKEONE.HLP Help file for program below.

MAKEONE.PRG Program to generate database template (schema).

USEONE.HLP Help file for program below.

USEONE.PRG Program to allow entry, editing, and querying of database after schema has been generated by MAKEONE.

CPRIMER.C Demonstration of VDI interface in C, and teaches basics of C programming.

CPRIMER.PRG Compiled version of above.

DVORAK.TOS Program to interpret keys as in DVORAK layout. Doesn't
            switch keycaps for you, however.

MEMTEST.C   Memory test program which additionally shows C access to
            memory parameters.

MEMTEST.PRG Compiled version of above.

QWERTY.TOS Program to revert keyboard layout to QWERTY format.

ST Public Domain Software Library

****** DISK #5 -- Applications ******

READ_ME The contents of this disk (what you are reading).

ADDRESS.DOC Explanation of following program.

ADDRESS.PRG Address and mailing list program that can additionally
             dial telephone numbers thru a smart modem.

AS68.DOC	Instructions for assembler below.
AS68.TTP	Public domain 68000 assembler!
DOODLE.DOC	Instructions for following program.
DOODLE.PRG	Simple color drawing tablet.
DOODLE.RSC	Resource file for above.
JOUST.PRG	Like the arcade game except no score and no sound effects. One- or two-player (requires joysticks).
LIFE1.DOC	Instructions for program below.
LIFE1.PRG	Monochrome version of simulation of Life. Cursor arrows set initial arrangement of live cells. 160 x 100 playing grid.
LIFE2.DOC	Instructions for below.
LIFE2.PRG	Color version of Life. Mouse sets initial configuration. Cells start white, then cycle thru colors.
NEO.DOC	User manual for NEO.PRG.
NEO.PRG	Atari's free color drawing program.
PIANO.PRG	Simulation of tones from piano keyboard drawn on the screen. The first two rows of the CPU keyboard are assigned notes over a two-octave range, and activate the sound chip when depressed.
SOUND.DOC	Instructions for the following program.
SOUND.PRG	A program which allows the user to exercise the variety of sounds from the sound chip. Nice user interface.
SOUND2.C	Another demonstration of the sound chip.
SOUND2.PRG	Compiled version of above.
STWRITER.DOC	Intro to STWriter.
STWRITER.PRG	Atari's word-processing program.
TARGET.PRG	Game in which players take turns in controlling angle of turret and speed of projectile in attempts to strike the other's headquarters.

****** DISK #6 -- Tutorials ******

READ_ME — Contents of this disk (what you are reading).

TUTORIAL.GEM — (folder) Tim Oren's *excellent* guide to programming in the GEM environment. Thus far there are nine chapters, each of which covers one or more areas. Accompanying most chapters is a file of untilities to aid in the use and understanding of that chapter's topics. I use these tutorials as on-line references to system-level functions.

- GEMCL1.DOC — Introduction to the tutorial series.
- GEMCL2.DOC — The window manager, redrawing, window control requests, sliders, bugs, dirty tricks.
- GEMCL2.C — C utilities to accompany above chapter.
- GEMCL3.DOC — Dialogs, bug alerts, buttons.
- GEMCL3.C — C utilities to accompany above chapter.
- GEMCL4.DOC — Resource files, object types, editable text.
- GEMCL4.C — C utilities to accompany above chapter.
- GEMCL5.DOC — Object trees.
- GEMCL5.C — C utilities to accompany above chapter.
- GEMCL6.DOC — Rasters, VDI operations, monochrome vs. color, device-specific formats, fringes, transformations, optimized raster ops.
- GEMCL6.C — C utilities to accompany above chapter.
- GEMCL7.DOC — Menu structures, dynamic menu entries.
- GEMCL7.C — C utilities to accompany above chapter.
- GEMCL8.DOC — Covers user interface issues such as fingertips, muscles, eyes, short-term memory, and chunking.
- GEMCL9.DOC — VDI graphics: polylines, rounded rectanges, arcs, solids, area fill.
- FEEDBACK1.DOC — Question & answer session, part 1.
- FEEDBACK2.DOC — Question & answer session, part 2.

CNOTES.DOC — Examples of C language constructs.

EARTH.NEO — An image of the earth as viewed from outer space.

FRACTAL.NEO The image of a fractal, which can be loaded into Neochrome and edited.

LINETEST.C Example of C program which performs graphics.

LINETEST.PRG Compiled version of above.

MEGABYTE.DOC Latest version of instructions on converting the 520ST to a 1 megabyte machine. Use at your own risk!!

MOUNTAIN.C Another exemplary graphics program; draws polygonal surface.

MOUNTAIN.PRG Compiled version of above.

RAM.S A ramdisk program written in assembler. Although this program assembled does not work on a machine with TOS in ROM, I include it for educational value.

TIPS.DOC Well-written collection of tips on using the ST aimed at beginners.

XMODEM.DOC A detailed description of the XModem protocol.

****** DISK #7 -- Applications ******

READ_ME         Contents of this disk (what you are reading).

MIDI            (folder)  Various programs and data files which make
                use of the Midi capability of the ST.

  SONGS           (folder)  Sample songs to play thru Midi.

    BANJO.SNG       MUSETTE.SNG
    CLEM.SNG        PREVIN.SNG
    EVITA.SNG       RAG.SNG
    MINUET.SNG      SANFRAN.SNG
    MOSCOW.SNG      SANJOSE.SNG

  4TH.BLK         Auxiliary (Forth) file for MIDIPLAY.PRG below.

  4TH.IMG         Another (Forth) file for MIDIPLAY.

  MIDI.TOS        Program to allow recording, playing, and monitoring
                  (dump-thru) of Midi port.

  MIDIPLAY.DOC    Instructions for using program below.

  MIDIPLAY.PRG    Plays songs in .SNG format on Midi port, and draws
                  piano keyboard which displays notes as they are played
                  with a different color assigned to each voice (device).

BIRDFLY.DOC     Instructions for using programs below.

BIRDFLY1.PRG    Program to simulate flight of bird.

BIRDFLY2.PRG    Same as above except bird can fly in front of any
                Neochrome image.

BIRD2.ANI       Data for above program.

BIRD2.NEO       Seascape image for above.

OTHELLO.PRG     Implementation of Othello where the ST is your opponent.
                Allows retraction of last move and adjustable level of
                difficulty.

OTHELLO.RSC     Resource file for above.

We just installed two SHD212 "prototype" 20Megbyte hard disks on our ST's. The speed really is impressive. Micro-emacs and an 8K file come up with about the speed that one expects of a RAMDISK.

The problem with head parking is very real. One of our office mates cycled the power on the hard drive without running the head parking program. The file system was trashed. We are now posting procedures and will soon install an iron maiden for the unfortunate souls who do not take heed!

I presume that compile, link execute benchmarks will be forthcoming, Bammi???

Dear Folks on net.micro.{amiga,atari16}:

There's this guy (an Atari-owner, and a rather proud one) who tells me something about since the original Amiga development work was done at Atari, that, with every Amiga sold, Commodore pays a commission of some sort to Atari. Is there any truth to this? Responses from people at C-Amiga and/or Atari (Mr. Dyer?) would be greatly appreciated. (Or anyone else who knows the truth.)

Much thanks,

Does anybody know of a good RAM CACHE program or algorythm?
Asynch read-ahead, and write would be nice, along with demand
based purging.

Such things are available for other machines, and appearantly
save you some of the grief of powering down the ram disk before
you've put it back on floppy. I've also heard they're real nice
with hard drives. I know very little about them exept that they
make a machine look like it's running faster.

Is this an OS/Driver hack?

The OS is not CP/M68K! If anything it could be considered GEM DOS with a customized BIOS. It so happens that GEM DOS has a number of similarities to CP/M. After all it came from the same folks.

I don't wish to attempt to prove by what "authority" I state this. I welcome
you to phone Richard Frick or Sig Hartmann at Atari for your proof.

Hello. I am wondering if it would possible for you to mail me one or
two of the files in the disks mentioned in your article. In particular,
I am very interested in the two files:

     GEMCL6.DOC
and GEMCL6.C

If you could upload either of the above to your system and then mail
me a copy, it would be greatly appreciated! If it is not possible,
thanks anyway! Keep up the good work.

Talking about the port of the C compiler from CP/M68k to GEMDOS...
CP/M68k does not have directories, while GEMDOS has. But no one thought
of this when they ported the linker. It seems to be impossible to link
files in different directories together. I use the atari hard disk for
development, and I (unix-addict as I am) like to have all things in the right
directories. Everything is fine, I have my \bin, \include, and \lib.
But to link a program, I have to copy my objects into \lib, cd to \lib,
link there and copy the program back into my directory. Granted, this is
all done by a command script, but it is a major pain in th *ss, though.
Obviously, the checks in the linker for correct filenames has not been adapted
to the different environment. Does anyone know if this will be fixed, or can
anyone give a patch to switch this stupid checking off ?

*** REPLACE THIS LINE WITH YOUR MESSAGE ***
The problem is not with the Ramdisk but with the version of tos you
are using. The later versions anf the rom tos fix the problem. One
caution about using floppies or ram disk to compile and link is
that you should have plenty of free space for temp. files. The linker
in particular does not tell you when it runs out of temp file space.
You realize that this happened when you end up with a ridiculusly
large/small .prg file after running relmod on the .68k file.

    Will someone from Atari on this net hold the programmers who
wrote link68 and ar68 upside down for a little while for me :-).
Seriously, when are you going to upgrade these two very weak links in
the dev system? My biggest objections are the speed due to the brain
damaged ar format (at least provide a ranlib), link not understanding
pathnames, and link not informing the user of some errors. In fact i
see no reason to have a relmod at all, link should generate the
correct output (Gemdos is not cp/m68k remember!).

I have done the 1meg upgrade for myself and a couple of others, but I
have yet to find a reasonable ramdisk! I am going to be doing a lot
of C and it sounds worthwhile.

Whose ramdisk do you use and where can I get one?? If it is public
domain can i send you some cash for your trouble in making a copy for
me? If it isn't public domain where can I buy one?

Also any pointers on how you set things up to use the disk would
be appreciated!

Thanks.

    Does anyone know how to make menus on the resource construction
set? When I add entries to a menu, there are large spaces between each
entry. How can you add entries without the large spaces? Is this a bug
in the RCS, or just me using it wrong?

                        Thanks for the help,

I have updated 3 machines to 1 meg, using TI and Mitsubishi drams.
On one of the machines one of the drams didn't work (anti-static foil
was used so I must assume the chip was bad from the factory). This
machine still booted (with 1/2 meg.) since the boot found bad memory
in the top 1/2 meg. As a developer, (i.e. SID debugger and schematics)
I found it relatively straightforward to find and fix the problem,
although time consuming. All of these used the (unnecessary?) 68
ohm resistors.

It is up to the individual to assess their level of expertise in
a mod like this, and/or their willingness to gamble on the outcome
and the possible steps they may have to take if things go bad.

My experience has been positive on the whole.

My developer's kit came with no documentation on how to use the RSC.
The following are just some things I found out by playing arround with

the RSC. For the sake of clarity, I call the objects in the menu bar 'items' and the individual objects within a menu item 'selections'.

 - When dragging menu items from the 'part-box' to the menu bar, place it to the right of the last menu item. If it overlaps any previous item, the menu items will be rearranged.

- You can set how wide the highlighted bar will be when the menu item is moused in the application program by dragging the lower-right corner of the highlighted area when the menu item is selected (highlighted) within the RSC. This also affects where menu item(s) to the right will be placed in the menu bar.

- You can resize the drop-down area by 'dragging' the lower-right corner. You can enlarge this area only if the area is empty. For example, when you first create a menu tree, there is already an item called 'File' with one selection ('Quit'). You would have to remove this item in order to enlarge the area. You can, however, shrink it even if it is not empty.

- Within the application program, when the mouse is over a selection within a menu item, the selection is highlighted. The width (and possibly height) of this highlighted area can also be set with the RSC. This is done by 'dragging' the lower-right corner of this highlighted area within the RSC.

To: ALL
Subject: CP/M68k vs TOS

I would like to thank everyone who helped with my question about CP/M68k versus TOS. As was to be expected, everyone was more then helpful. Consider an indication of just who owns STs!

However, I guess what my friend and I both feel was basically correct. Atari did NOT write TOS, it modified CP/M68k. While I realize writing an OS is no small feat, I think where the question came in is that it was so vehemently stated that TOS is not CP/M68k that we were under the impression that it was supposed to be a total rewrite (effectively) which resembled it.

In the end, it's no great loss anyhow as the world has not been overwhelmed by the powerful software available for CP/M68k anyhow. (As soon as you see the "CP/M" in front you should've figured, right?) but as "What software does it run or is it compatible with?" becomes more and more the question asked nowadays, technically speaking CP/M68k programs cannot be included.

Where's Unix System V anyhow. It's about time to flush this single user nonsense anyhow!

To: info-atari16@su-score.arpa
Subject: Re: Full Screen Editor Rqst (GNU Emacs)
~~~~~~~~~~~~~~~~

Not only is the GNU Emacs source huge (the tar file distribution is
about 6 Megabytes), but the amount of peripheral information needed to
run it is big. Various important sizes:

```
Sun 2 executable   >600K (stripped, optimizer off, 470K of
                      that is C, the rest is Lisp and data)
Peripheral stuff   >3.8M (could probably be cut to about 1.5M)
```

One person here has ported it to his AT&T Unix PC. I still don't know
how he shoehorned it onto that 10M disk, but he did it.

The things that make you want to put it on your favorite box are that
1) it is the best Emacs around,
2) it is currently being actively supported and enhanced by some good
   people,
3) it is being ported to lots of different environments (I am aware of
   attempts to move it to IBM/370 Unix, the Cray-2, VAX/VMS, and a wide
   variety of System V and 4bsd boxes, and
4) it's free.

When large enough hard disks become available (20 to 40M) for the ST,
it will probably make sense to port it to the ST.

i) Terminating a running program :
    Is there a way to terminate a running program by typing ^C or
    delete ? I notice that many programs can be terminated with ^C,
    but this doesn't work with every program. I understand that one
    has to make AES calls in order to sense a ^C. But if a program
    is stuck in a loop which does not contain an AES call, there is
    no graceful way to terminate and exit.(I think it should be the
    responsibility of the OS to intercept a ^C and stop the program.)

ii) Updates to Developer's package :
    I had returned the 'non-disclosure agreement' soon after buying
    my developers' package in October 85.   I have not received any
    updates to it since. Have there been any?

iii)uudecode, uuencode:
    Someone remarked about problems with uudecode. I have also been
    totally unsuccessful in getting uudecoded programs to work. I'd
    picked up the (IBM) C source off the net and then adapted it for
    ST. The program seems to work correctly for concocted test files.
    Is it possible that uuencoded files are being damaged in transit?
    If someone has already solved this problem, please help. Else I
    shall go through the debugging procedure and post the program
    (along with a BASIC version).

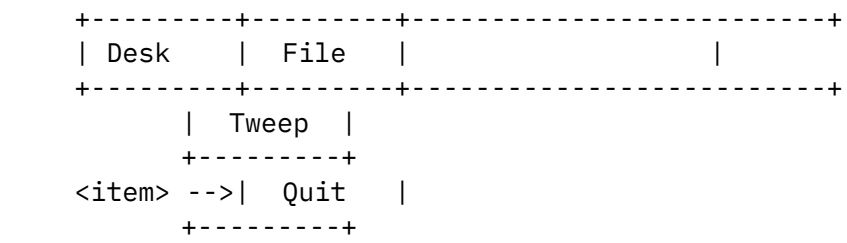
Just to clean up the terminology:
Robert's "items" in the menu bar are called "titles"
and his selections are really called "items" in GEM/AES lingo.

           <title>
              |
              V



See an exanple of a MENU tree in the .C file generated by RCS.

At the end of this message is the source for a 360k ramdisk.
I got it on the net a long time ago and have been using without
any problems for quite a while.

In terms of how I use it, it depends on what I am working on.
If I am working on ST Basic and 1st-word together, which I do
quite often, put both of them on the ramdisk. This allows me to
switch from one to the other very quickly (in seconds!). When
compiling, I put most of the compiler and linker on the ramdisk,
leaving the libraries on floppy. I also put ME on the ramdisk.
This leaves enough room on the ramdisk to put the source and
compile very quickly. Linking takes time but I find that I
usually compile a lot more than I link (finding syntax errors,
etc.). I also have a 512k ramdisk (changed the entries in the
BPB structure). However, I can't seem to find the source right
now. If you want the 512 k ramdisk, I can mail you the uuencoded
binary. In fact, I can also mail the uuencoded binary for the
360k ramdisk if you wish.

============ source for 360k ramdisk follows ============
```
/* RAM  DISK ACCESSORY Version 1.3 - 1986 Feb. 1.

   Original:  Version 1.1 Gert Slavenburg, Mountain View, CA.

   Modified:  1.2: Reginald Knighton (213) 473-5202 [voice].
              improved performance by over a factor of 3

              1.3: E S Fraga - cleaned some things up.  Does not
              copy A: on boot up any more.  No beeping either.
```

```
   For Atari 520ST with RAM extension to 1 MByte.
   Link this program with accstart,%1,osbind,vdibind,aesbind

   This is the first, experimental version of the RAMdisk. It should
   be installed as a DESK ACCESSORY on the Bootdisk. Before re-booting,
   and thus activating it, the menu entry "install disk" should be used
   to install drive "D" with icon-label "RAMDISK". Then save the desktop to
   make the newly installed drive permanent.
   Now re-boot end enjoy. (write protect if you're paranoid - I am)

   You may get annoyed by my trick to let the RAMdisk give a beep every
   30 seconds. This was a debugging tool for me to see if it's still
   alive, and I get worried now if I don't hear it anymore...
   To remove it, just replace the "beep" statement in procedure "sleep".

   known bugs :
   1) GEMDOS refuses to do full diskette copy to/from the RAMdisk. Don't
      know why it does that, since the BPB's are identical.

   Lots of fun - Gert

If by "entries" you mean "titles", you can edit out the spaces in the title
(start by double clicking the title).

If by "entries" you mean "entries", you can resize the area for drop
down menus by holding down CTRL and dragging the bottom right corner
of the area. Entries can be positioned anywhere within this area,
on *line* boundaries only.

     Have you noticed that the Modula compiler 'modula.prg' will
only run if it is put in the root directory of a drive 'd:'. It
refuses to even startup if put in any sub-directory. The linker
and editor work OK in subdirectories though. I guess it is due to
the overlay directory, which also has to be in the root directory.
On my hard disk this does not fit the usual \bin \src etc scheme of
things. It is obvious that the designers never considered hierarchical
file systems. The file dialogue are driving me crazy.

     Has anyone else got the error '- compiler error 2', while
compiling a program. This is followed shortly with a dialog box saying
'Run Time error #9'. In the manual run time error #9 says 'Program
Halt'. Any hints??

More questions: any answers will be much appreciated.

Suppose we have

```
TYPE
     word = ARRAY [1..15] of CHAR;
VAR
     s1: word;
     s2: ARRAY[1..10] of word;
....
```

and we write

```
     IF s1 = s2[i] THEN
               ^ operation with incompatible type (140)
```

The Tdi compiler gives the above error, but the Powell m2 compiler does not object. Who is right? (reading Wirths or Thalmann's book didn't give me any answer).

Also

```
TYPE
     word= ARRAY [1..20] OF CHAR;

..
PROCEDURE init(i:INTEGER; w:word);
VAR
    x:word;
...

x := w;
..

END init;

     init(1,'Something          '); (* 'twenty chars in string' *)
               ^ type incompatibility (128)
```

gives the above error.

if i change the type declaration to

```
TYPE
    word = ARRAY [0..19] OF CHAR;
```

The program compiles. Powells compiler of the Vax does not object to either Type declaration. Again who is right?

I better stop before i break my '?' key. Any answers will be much appreciated.

The book just reviewed might be useful to someone without the dev kit
but my feeling is that it is far too elementary to be useful to anyone
with the dev kit. The following line taken from the book gives you an
idea of who the book is targeted for: "AES and VDI are nothing more than
libraries (along the lines of the Library of Congress) of functions and
program routines."

If the book sold for $1.95 I would say buy it. But at $19.95 it is a
real steal and you are the victim.

  MicroEMACS was supplied to me by Atari(UK) with the developement ki
It is about 28k object code plus 128k documentation.
I much prefer '1st Word' the word processor distributed in lieu of
Gemwrite.

They are on the way. We started to ship within the past week. The first
batch was delayed because (and you'll never believe this one) the airplane
made a stopover in the Phillipines. A LOOONG stopover.

The first load is completely spoken for, but several more boatloads are
expected soon. So tell your dealers to get their orders in place!

  Local dealers have had publicity about CAD software with an inbuilt
spreadsheet and graphics language. They have not been able to get their
hands on the software or documentation despite 3-4 months trying. Does
anyone out there know anything about this product or company?

Keywords: Atari ST monochrome monitor

     For anyone who is still sceptical about the lack of interlacing on the monochrome ST, Degas can be used to easily set each odd line of the screen to white. Then the finger waving test can be used to establish that the rate is

71 Hz for either all white or only odd lines white. The figures I got with a stop watch were 71 Hz plus or minus about .2 Hz. This convinced me entirely!!

********* Richard Mangeur de Lion - King of England (12th century) *****

The comments below were made upon first using the OSS Pascal compiler. That was about a week ago. Since then I've found a couple of things I am not entirely happy with. For instance, the "eoln" function does not work in the same way as in normal Pascal. And there are one or two aspects of the development cycle that are not quite deluxe. But overall, this seems still to be by far the best way I know to write programs on the ST. It is still a real pleasure to use it.

Comments on the OSS Pascal compiler:

Folks! This is one stunning compiler. A positive pleasure!! I'm beside myself with amazement and delight. Chuck out your old Vaxes, folks. Or use them as intelligent disk drives. Why suffer any longer with that user-hostile junk? Perhaps I should try to calm down......

Just today I received OSS Pascal in the mail (1 week after ordering it, costing $50.) The documentation stunned me. The best documentation I've seen for micro, mini, or real computer compilers in 15 years of programming. And then I gave it a test drive. It's just what I always wanted.

In the middle of editing, you just push [F9] to save,compile and link (with optional maintenance of a backup of the last version, which makes me homesick for VMS version numbers on the files.) Compare that to mouldy old DRI C! It has standard Pascal plus all of the extensions that any rational person would want. And the variations from the standard don't require extensive reading of the documentation to convert old programs (like the ST Basic, for instance). The editor is good, and well integrated

with the rest of the development process (merging files, storing portions, moving to the compilation phase, indents, backup mode, search/replace, insert/replace modes, etc.). To run an old VMS program from years ago, I only had to change "varying" type to "string" type, and move the filename definition for an input file from an "open" statement to the "reset" statement - all very clearly and accurately explained in the manual. And then it ran!!! There was once a time when languages were supposed to be machine-independent. And this compiler brings a bit of that back to the ST. (As opposed to Basic.)

The manual even tells how to interface to assembly language and C (use of the stack, register usage etc.) And the compiler can be told to use lower case function names preceded by underscores so as to be compatible with DRI C. Bios, Xbios and Gemdos are accessed be function number, which means the Atari documentation is prabably necessary, and VDI/AES are called by almost the same names as in C, except that the two seem to have been integrated here. The C routine appl_init seems to have been replaced by init_gem, for instance.

Other things I like: underscores allowed in identifiers, identifier names case-insensitive, a compiler directive to allocate stack/heap space, lots of different optional runtime checks for stack overflow, range-checking, pointer-range, an include directive etc. etc. The compiler will also name the program .prg or .tos as required by the saved options file.

Using the .tos option, it's just like using the old Vax. And all of the mouse/window stuff seems to be included in the runtime library.

I hope it isn't improper for me to write all of this. But I thought some of you out there would like to know what you're missing.

Actually, I must admit that I would have liked to be able to mix Pascal and assembly language freely, but you can specify in the saved options file the list of code to be linked at link-time.

Incidentally, I am not biased or self-interested or doing anything else of an underhand nature in writing all of this.

so long ..... Alan Kennington

Someone recently suggested a boycott against EA even when they DO
start programming for the ST. I would like to point out that this
is a self-defeating argument. Sure there are other software companies
out there programming for the ST. We want more! EA will *not* "go down
the tubes" without ST customers. They write for enought machines that
they don't really care if we buy their stuff or not. However they DO
produce good software. Much of which would not be available from other
companies. My suggestion: buy from them if it is the product that you
want, don't if it isn't. A boycott of them after they cave in to demand
and start writing ST software would be cutting off your nose to spite
your face.

BTW: This boycott call was posted to INFO-ATARI8. Possibly because the
original EA letter was posted there. The EA letter was a general interest
item, and should have been posted to both groups (I don't know if it was...).
Someone flamed the poster, saying keep ST stuff out of the ATARI8 mailing
list. I sent a note to him saying it was general interest. HOWEVER, the
boycott call was DEFINATELY ST-oriented, and should have been posted
to INFO-ATARI16.   I know this split is confusing folks, but I am sure
that you can do it if you try.....

I had an unpleasant experience with two Atari 520 STs
(the standard monochrome configuration), I received through
mail order. The first one I got showed a screwy display a few minutes
after I turned it on for the first time. I sent it back the next day
for exchange. 10 days later I received another one, whose display develops
a slight blurr about 5 minutes after turning it on. About 5 minutes later,
the blurr goes away, and the picture stays normal for the rest of the
session. The same thing happens with remarkable regularity (plus/minus
one minute - I timed it) every single time I turn it on after being off
for several hours. Recycling the power of either the computer or the
monitor after the first 10 minutes does not spoil the image.

Has anybody seen this problem before? Atari hasn't.
Any fixes? Please answer fast, I only have a 10-day exchange period.

To all the hackers out there in ST land.

I am posting this in the hope that someone can provide me a few clues to the following questions:

1. Has anyone tried to get their own hard disc up and running on the ST either 520 (512k or upgrade to 1024 k) or 520+ (European 520 with 1024k)?

2. What hard disc controller and also what make and size of hard disc did you use? Is there a limit to the size of the hard disc the ST can handle?

3. Does the ST operating system, TDOS, come with software support for the SCSI/SASI hard disc bus built into the ST?

4. If there is no built in hard disc software support is there any mention in the developer's manuals of how to hook up and run a hard disc.

5. How does the Haba Hard Disc for the ST handle the software required to run the hard disc? Is there overlay or other software provided by Haba for TDOS or is TDOS smart enough to look at the hard disc port on cold boot? If it is can you select to boot from the hard disc and does this provide autoexec software capabilities similar to that available on CP/M and PC machines?

6. What sort of hard disc controller do Haba use? Has anyone had a look inside their box?? Is it their own design or do they use a WD1000, Shugart 1610 or similar SCSI/SASI type controller?

7. In the November 1985 Antic magazine there is an article which shows you how

to attach a 5 1/4" DSDD 40 or 80 track drive to the ST. Has anyone had a go at doing this yet? If so, were there any hassles either in the hardware or with the operation of the drive in the system? Are there any limitations to the use of this type of drive on the ST, ie. incompatability with the OS, sacrifice in file transfer speed, file transfer size limitations?. Could you use two 5 1/4" drives in place of the 3 1/2" drives if you have TDOS in ROM? I would prefer to have 700k odd capacity on discs that costs 1/3 of the 3 1/2" price.

If these questions have been asked and answered previously maybe someone could mail me a copy privately. If not, I am sure that there are others out there somewhere who would like to have a go at rolling their own hard disc and maybe adding a 5 1/4" DSDD disc drive as well.

For anyone interested in the 5 1/4" drives there are 96TPI (80 track) full height 5 1/4" drives available through mail order houses for about $US50 at the moment. With a case, power supply and cables you can have drive up and running for well under $US100. Beats the ATARI price by quite a few bucks and if you need it (you might want to upgrade your PC, XT, AT to a real machine) you will have built-in 5 1/4" IBM disc reading capability for tranfering ascii text files to your ST.

Thanks in advance for any help.

You are absolutely right. This is a major pain. What's the point in having
an organized directory if your tools can't make use of it? We are attempting
to get the compiler/linker/etc programs either fixed or changed so that they
accomodate hierarchical directories.

In the March BYTE, there is an article on the 1040ST which mentions
that at some point there will be a socket in the 1040 motherboard for
a graphics chip followed at some time later with an actual chip to go
into the socket. I don't know about anyone else, but if it will cost
me a lot of money to exchange my motherboard for one with a socket or
if I don't know how much it will cost to upgrade then I'll wait a few
months (or more) to get the real thing.

Will someone at Atari please clarify the availability of the socket
and the availability and capabilities of the forthcoming graphics chip.

  Concerning the availability of the 1040ST, at last night's (3/3/86) meeting
of the Bay Area Atari Users Group, a 1040ST with a hard disk was demonstrated
by San Jose Computer. The representative mentioned that they recieved 20

ST's last friday but that by today (monday night) the unit he was showing was
the only one left!

You have to have a formatted Atari diskette with NO files, and NO volume
label on it. This will work fine. I usually find it works even better on a
newly formatted diskette, rather than a normal GEMDOS diskette with all the
files erased.

Getting files onto the disk is tricky. I uploaded the source to a TOS->CP/M
file transfer program that includes a slight bug. The program works in my
testbed, but when I try to run it on my ST, it's always off by one block.

I don't know exactly how fast it is, but it seems extremely unlikely
that it matches a 4MHz Z80. More like a 1MHz Z80.

In my list of utility programs on Disk #4, I included four programs
which I should not have: DBMASTER, CONTROL.ACC, BREAKOUT.ACC, and
VT52.ACC. These are in the process of enhancement by Atari, who has
requested that they not be placed in the public domain. (DBMASTER
may be a product in the future.) I apologize for the error; I will
place other utilities on Disk #4 in their stead.

Keith

The CLI command interpreter posted to the net contains the following messages embedded in the executable file:

    Rising Star Industries, Copyright (c) 1985

and also the line:

    RSI Command Facility V1.01 9-20-85 MGW

This seems to suggest that this is a proprietary product, and therefore should not be distributed over the net. Is this true, or has Rising Star Industries given blanket permission to distribute it?

I do not wish to suggest improper behavior on the part of the poster of this article, nor on the part of the SYSOP of the BBS where he states he obtained it. However, we should clarify its status before allowing it to be further distributed. I'm not familiar with Rising Star Industries. Does someone know how to contact them and determine if this thing is legit?

This message was returned to me when I tried to address it to
both INFO-ATARI8 and INFO-ATARI16 at the same time. My mailer
is a bit dense at times.... I have recieved one copy through
channels, and am assuming that INFO-ATARI8 got it, and that
INFO-ATARI16 has not, therefore I am reposting this only to
INFO-ATARI16. If I have guessed wrong about which list got
it, I apologize in advance.

Ok, there have been some mis-postings, and some (largly inaccurate)
flames about them. Let's lay out the ground rules:

   1) INFO-ATARI8 is for the 8-bit machines
   2) INFO-ATARI16 is for the 16-bit machines
   3) INFO-ATARI is currently synonymous with INFO-ATARI8
      (contrary to the recent flame, messages are not
      posted FROM INFO-ATARI, they are posted TO INFO-ATARI)
   4) INFO-ATARI8-REQUEST, INFO-ATARI16-REQUEST, and INFO-ATARI-REQUEST
      are ONLY for posting bookkeeping notes to. Add to list. Drop
      from list. They are NOT for posting messages to, hoping someone
      there will figure out where it should go for you. Lets use a
      little judgement and keep our mailing list operators lives a
      little easier.

My own vote is that INFO-ATARI (no number) should be a master post to
both 8 & 16 bit lists, and used for general interest items. This is,
however, only my opinion on how it *should* be, and does not reflect
the current status of the mailing list.

There has been some misteaks on posting to the lists, but the flames
have been equally irresponsible. There was a posting on INFO-ATARI8
about a letter from Electronic Arts that said they will start publishing
for the 8-bit machines again. It ended with the hope that if we keep
up the pressure they will do some for the STs. This was promptly flamed.
That flame was out of line. The bulk of the message was about the 8-bit
programs they were about to start. There was, however, a reply to this
msg about starting a boycott of EA, to spite them. This was directed
to the ST owners, but due to the laziness of the poster (I am assuming
he used a 'reply' function in his mailer) it was posted only to the
INFO-ATARI8 list. This too, was out of line. A more recent flame
was complaining about a posting from 'INFO-ATARI ... the ones who
split the list'. This is flat-out wrong. As I pointed out above
the INFO-ATARI address is synonymous with INFO-ATARI8. It was addressed
wrong, but it was NOT from 'the guys who split the list'.

How about we all be a little more responsible both with our addresses
AND our hair-trigger responses when something goes wrong?

Keywords: How do you get provisions?

I hope you don't mind the game question here, but I think this problem
might be ST specific (I asked this question to someone who had the
Apple II version long ago, and he didn't have this problem).

I can't seem to get any provisions. I always starve to death. I see
wandering shopkeepers who ask me if I want to buy apples, but I can't
find a way to buy them. I just keep getting the same query.

Thanks.

You might want to try a simple short term fix for this type of problem that
is available on the Mac. Andy Hertzfeld wrote a patch to the open routine
that searches all directories if it cannot find the file in the current
directory. This allows many pre-HFS programs to work with the new Mac ROMs.
I do not know if this kind of patch is as easy on the ST as it is on the MAC,
but it might be worth a try.

Has anyone been able to move uuencoded files from the net to a 520ST and

get them to run? I've downloaded the assembler, the clock, and micro
EMACS, uudecoded them and tried to run them. The screen clears (micro
EMACS asks for parameters since it is a .TTP file), the disk whirls,
then I get the desk top back. I would suspect the uudecode program, but
a dump of the decoded files show character strings that are readable among
a lot of stuff that is not readable. Since I just received the TOS ROMs, I'm
going to install those and see if they make any difference. Any other
suggestions?

I was told by atari that there is no socket in the current 1040's and
this chip will not be for a while... I was assured that one could put
one in eventually but that it would involve a `kludge' I would not
put off buying a 1040 on this one. after all with custom VLSI, schedules
are a mystery to even the people intimately involved. They did say that

they had first silicon however... They also as an aside told me that
on the `Amy' chip, the 16 bit audio chip, they punted on it after
difficulty in making the silicon do what they wanted; They sold the design
to a third party. Hopefully they are not going to be made in the
Phillipines ;-)

*** REPLACE THIS LINE WITH YOUR MUSHROOMS ***

  Well, I don't (yet!) have my ST, but I want to be able to plug it in and start programming immediately (1/2 :-), so I'm going to be ordering software soon. Here's a very short summary of what I've seen here so far on the subject of languages:

TDI Modula-2: Exciting, but has a bizarre object file format

OSS Personal Pascal: Great! Impressive! Nifty!

DRI C: Slow and lacking

Megamax C: It exists

Lattice C: Real Soon Now

  Is that all anybody knows about?! I'd rather program in C than Pascal, but so far I'm leaning toward the TDI Modula-2 compiler. Is there any other C out there? What about assemblers?
  Since the language and compiler themselves make up only a part of a development system, I'm also very interested in the less heralded things, like editor (if there is one), edit-compile-link cycle (speed, ease,...), documentation, library routines, etc. (The OSS Pascal and TDI Modula-2 reviews have been really good about that; thanks, to those of you who've posted). Any information would be appreciated (post things of general interest; send obnoxious comments and flames by E-mail).

My personal view of the developer's kit:
It may have been the only game in town at one point, but that's not true anymore. From the reports on the compiler and documentation, it's not worth the $300 price. Are there any plans to either reduce the price, tidy it up, or unbundle the components? Also, both myself and another couple of people I've talked to see an attitude on the part of Atari of "if you didn't pay us $300 to be conferred the title of Developer we won't play with you." Is this a warped perception? [This one should probably be answered by E-mail!]

In my list of utility programs on Disk #4, I included four programs
which I should not have: DBMASTER, CONTROL.ACC, BREAKOUT.ACC, and
VT52.ACC. These are in the process of enhancement by Atari, who has
requested that they not be placed in the public domain. (DBMASTER
may be a product in the future.) I apologize for the error; I will
place other utilities on Disk #4 in their stead.

Keith

The 1040ST will NOT have a graphics chip. A chip under development should
appear in a more costly computer later this year -- a new model.

However, we are also developing an add-on board for the 1040ST to adapt it
when the new chip is out. The cost of this add-on is expected to be similar
to the differential between the 1040ST and the new model.

No word on the adaptability of the 520ST to this chip -- but my guess
<unofficially> is that it will be equivalent to adapting a 1040ST.

We can't diagnose your problem without more information. Can you
tell us everything you do exactly in sequence right down to how you
move the file from the net to whatever and how you prepare the file for
decoding. I have tried uudecode several times and it has always worked.
If we get to the bottom of this in public alot of people should benefit.

Whatever you do - do not destroy the original files - there is still

hope.

"Where there is a will there is a way"
                    - mothers all across America

P.S. include all equipment involved

One last thing - it is very important that we all get together and figure
out this UUDECODE problem because a whole lot more UUENCODED stuff is
coming down the pike real soon now!

Below is a catalog of the Bloomington, Indiana ST User's Group Public Domain software. We are willing and happy to place anything reasonable in size on the net for all to scoop up. Please look this list over. If you see something of interest, mail me a note indicating such (franco@indiana.CSNET). We will put anything that is mentioned by a large number of people on the net (even if it has to be UUENCODED and provided it is not too big - the bird demo (bird flying across the screen), for example, is pretty big - I will have to check to see what squeezing does to it).

BLOOMINGTON ST USERS GROUP
Public Domain Software Index
2/15/86

System:

   TOS.IMG
   DESKTOP.INF

Accesories:

   DESK1.ACC   -Control panel
   DESK2.ACC   -Breakout (game)
   DESK3.ACC   -Spooler (works only in desktop)
   DESK4.ACC   -RAMDISK (360K) for the 1 MEG upgraded ST without TOS in ROM
   DESK5.ACC   -VT52 terminal emulator
   DESK6.ACC   -Fontloader
   DESK7.ACC   -Displays amount of free RAM
   PUZZLE.ACC -15 Squares Puzzle
   CLOCK.ACC   -Digital Clock
   MRAMDISK.ACC-RAMDISK (100k - inf) Works with TOS in ROM
   SNAPSHOT.ACC-Takes snapshot of screen in DEGAS format
   CALENDAR.ACC-Displays current day within current month - use mouse to change
   TTOOL.ACC   -File, Memory and Sector Editors - needs work

Languages:

   BASIC.PRG   -100K Basic interpretor executable (Atari supplied)
   BASIC.RSC   -Resource file for above
   TBI68K.TOS -Tiny BASIC - allows lots of array space
   LOGO.PRG   -100K Logo interpretor executable (Atari supplied)

```
   LOGO.RSC    -Resource file for above
   A68.TTP     -Assembler
   XLISP.TTP   -Public Domain XLISP
   FORTH.BLK   -Dragon Group FORTH demo disk...full blown FORTH
   FORTH.TOS   -       minus file transfer capability
   FORTH.DAT   -
   PROLOG.LSP  -PROLOG built ontop of XLISP (slow)
   FORTH.TOS   -PD forth (different from previous FORTH.TOS)
   KERNAL.TOS  -Subset of the above

Programs:

   FIBON.LOG   -Computes fibonnaci numbers.  Used as benchmark, test stack
   FLAKY.LOG   -Draws snowflakes (from ANTIC)
   HANOI.LOG   -Solves Tower of Hanoi Problem graphically

   BUG.BAS     -Bug wanders in search of food, leaves trail.  Test RND
   BUG1.BAS    -Bug wanders in search of food, leaves no trail.  Test erase
   BOUNCE.BAS  -Ball is bounced against floor. HZ motion, CoRes < 1
   CIRCLE.BAS  -Builds many concentric circles.  Speed test for Basic
   ENIGMA.BAS  -Encode/Decode secret messages based on German WWII machine
   FIBONACC.BAS-Computes fibonacci numbers recursively.  Test stack, speed
   GRAVITY.BAS -Path of spaceship near star of great mass, leaves trail
   GRAVITYW.BAS-As above except that spaceship bounces off screen boundaries
   ITSYBITS.BAS-Plays itsybitsy spider.  Test of sound chip
   PI.BAS      -Computes integers A,B s.t. A/B is nearly pi.  Speed test
   SCALES.BAS  -Test of sound chip
   3CONES.BAS  -Three cones generated with sound
   SILENT.BAS  -Plays Silent Night (MIDI port only)
   MOUSE.BAS   -Mouse demo
   SOLIDST.BAS -Draws perspectives of objects...can use objects in .DAT below
   SHIP.DAT    -Used by SOLIDST.BAS
   XWING.DAT   -Used by SOLIDST.BAS
   TIEFIGHT.DAT-Used by SOLIDST.BAS
   VDITST.BAS  -Does as named
   MEM.BAS     -Some sort of memory tester
   FINAN.BAS   -Package of about 20 programs for managing your finances
   MOL.BAS     -Molecule viewer - needs .DAT files below
   NACL.DAT    -Sodium Chloride
   B10H14.DAT  -I should mention that some of these are mislabeled
   C7H7O2N.DAT -Another molecule
   CRC6H6.DAT  -Another molecule
   4B5H7.DAT   -Another molecule
   MOL7.DAT    -Another molecule
   BIORYT.BAS  -Find your biorythm curve for any day - even before you were born

   ART.LSP     -
   EXAMPLE.LSP -Object example
   FACT.LSP    -Computes Factorials (benchmark)
   FIB.LSP     -Computes Fibonacci Numbers recursively (benchmark)
   HANOI.LSP   -Solves tower of Hanoi problem
   HDWR.LSP    -Hardware objects, mix and match to create design
```

```
IFTHEN.LSP  -Animal world expert system (small)
INIT.LSP    -Required at startup of XLISP
OBJECT.LSP  -Object example
QUEENS.LSP  -Solves n-queens problem
QUEENS2.LSP -Solves n-queens problem with graphical output

LIFE.S      -Source for game of LIFE (assembler)
LIFE2.S     -Source for game of LIFE (assembler)
RAM.S       -RAMDISK source
HI25.S      -25 lines of text in Hi-Res mode
HI50.S      -50 lines of text in Hi-Res mode

Word Processing:

STWRITER.PRG	-Atari supplied word processor
STMAN	-Manual for STWRITER
QUICKREF	-Quick reference section for manual
XYZZX.TXT	-Set printer parameters
STCONFIG.TOS	-Creates XYZZX.DAT from XYZZX.TXT
XYZZX.DAT	-Used by STWRITER to send proper esc sequences to printer

```
   STWCARD.TXT
   TEMPLATE.STW-Template to be placed over keyboard - shows f-key defs
   DRIVRTST.STW-Puts printer through its paces for evaluation

Picture Processing:

   NEO.PRG     -Like McDraw except in color and with some features missing
   SLIDENEO.PRG-Presents slideshow of .NEO files
   SLIDE.PRG   -Presents slideshow of .PIC files (see Demos)
   WIND.PRG    -See pictures singly in windows (for .PIC files)
   WIND.RSC    -Resource file for above
   SHOWPIC.PRG -
   READPIC.PRG -Shows NEOCHROME pictures individually without a window
   NEOCON.TTP  -Converts pictures from DEAGS format to NEOCHROME format

Pictures:

   AAFAUCET.PIC-Water faucet in same room occupied by robot in ROBOTTV.NEO
   AAFLAG.PIC  -American flag and Atari logo
   AAREPORT.PIC-Weather map (very pretty - one of JF's favorites)
   AATRUMP.PIC -Trumpet (pretty)
   AAWORM.PIC  -Worm goes for a walk (interesting)
   AMIGA.PIC   -Atari figure pulls switch on Amiga LOGO sending it down and out
   ANGE1.PIC   -"Angel" (ugly angel but shows off shading ability of NEO)
   APLATE.PIC  -Indiana License Plate with ATARI 520ST written on it
   ATARI.PIC   -Atari logos all over the place (JF's least favorite)
   CHAOS.PIC   -What title says it is
   DEGAS.PIC   -Sample of FONTS available in DEGAS
   DRAGON.PIC  -Picture of a dragon fighting two warriors
   GHOST.PIC   -Ghostbuster LOGO
   HOUSE3.PIC  -Modern house in forest at Christmas
   JOCKEY.PIC  -Jockey riding Sofa (well done)
   SPIRAL.PIC  -(not terribly appealing)
   SAILBO.PIC  -Sailboats on sunny summer day
   SPACE2.PIC  -Four spaceships (not very appealing)
   SUPERM.PIC  -Picture of Superman before an American flag
   WHEELS3.PIC -Automobile against stark blue sky (ugh)
   AAFALL.NEO  -Waterfall at twilight (one of the best - animates well)
   AAINSECT.NEO-Large mothlike creature
   AATRAIN.NEO -Blue steam engine (not the greatest)
   CHROME.NEO  -Neochrome ad (not very interesting)
   FRACTAL.NEO -Mild technical interest
   GREATWAV.NEO-Large ocean wave (mildly intertesting, so-so color)
   MAP431.NEO  -
   ROBOTTV.NEO -Robot watches TV as canary and comet look on (cute)
   SCICOVER.NEO-Fractal generated cover of some issue of Sci Am

Pictures with sound:

   1ALITE.PIC  -Title frame of Audiolite demo
```

```
   2ALITE.PIC  -Elves opening castle doors
   3ALITE.PIC  -Inside room with fireplace clock
   4ALITE.PIC  -Inside room above with encased snowman
   5ALITE.PIC  -Inside room above with encased skier
   6ALITE.PIC  -Picture of Trumpet
   7ALITE.PIC  -
   8ALITE.PIC  -
   1ALITE.SNG  -Song accompanying 1ALITE.PIC
   2ALITE.SNG  -Song accompanying 2ALITE.PIC
   3ALITE.SNG  -Song accompanying 3ALITE.PIC
   4ALITE.SNG  -Song accompanying 4ALITE.PIC
   5ALITE.SNG  -Song accompanying 5ALITE.PIC
   6ALITE.SNG  -Song accompanying 6ALITE.PIC (Pachebel's Canon)
   7ALITE.SNG  -Song accompanying 7ALITE.PIC
   8ALITE.SNG  -Song accompanyong 8ALITE.PIC
   ALITE.PRG   -Runs the Audiolite demo (one of the best demos around)

Animation:

   BIRD.PRG    -Bird flies across screen (beautiful)
   BIRD1.BRD   -Background picture (any NEOCHROME file will do relabeled)
   BIRD2.BRD   -Secondary picture shown between flights (can be same as above)
   BIRD2.ANI   -The bird file

Demos:

   ACSKEL.PRG  -Developer kit demo
   APSKEL.PRG  -Developer kit demo
   ARTWORK.PRG -
   ARTWORL.PRG -
   BOINK.PRG   -Now classic bouncing r/w checkered ball against grid bkg
   CHKDMO.PRG  -Checkwriting demo from HABA (use lo.pic, lo-res)
   CHECK4.RSC  -Resource file for above
   CHESS.PRG   -Plays a game of chess while you watch (nice effects)
   COSINE.PRG  -Lines appear to move accross screen in beautiful pattern
   CUBE.PRG    -Cube shrinks, expands, spins.  Demonstates shading changes
   CUBEMANU.PRG-Manually control the cube of the previous demo
   DBMASTER.PRG-Make labels
   DEMO1.PRG   -
   DRDOODLE.PRG-Incomplete drawing and typing program
   DOODLE.RSC  -Resource file for above
   EFFECTS.PRG -Bombs system
   FIREWRKS.PRG-Move mouse to position, left click to set off
   FRACTAL.PRG -Generates pictures using fractals (very slow)
   FRACT1.PRG  -Another fractal program
   FRACT2.PRG  -Another fractal program
   FRACT3.PRG  -Another fractal program
   FRACT4.PRG  -Another fractal program
   GEMDEM.PRG  -Builds fractal tree, sierpinski, etc.
   GOLDFISH.PRG-Goldfish swims around monotonously
   GRSHOP.PRG  -
```

```
   HEX.PRG     -Many colors filling many hexagons - lots of movement
   LO.PIC      -Check picture for check writing demo
   LOWDEMO.TOS -Interesting demo
   MANDEL.PRG  -Mandelbrot example
   MENUTST.PRG -Play with menu driver
   MENUTST.DEF -Goes with above picture
   MOVELN.PRG  -Animation of polygons you create
   MOUNT.PRG   -Draws mountains out of polygons
   NEWSIN.PRG  -Like COSINE above
   PIANO.PRG   -Piano keyboard allows one note to be played at a time
   PIECHART.PRG-Produces piechart to play with
   PIEMAN.PRG  -Slices of a pie move in and out asyncronously
   QUIX.PRG    -String art
   QUX2.PRG    -String art
   SDEMO.PRG   -Siren, gunshot, other sound effects
   SOUND.PRG   -Move mouse to change frequencies of two tones
   SPIRAL.PRG  -Create a spiral to suit your taste
   STARRAID.PRG-Ad for STARRAIDERS game or something like that
   STARDEMO.PIC-Picture that goes along with above
   STCALC.PRG  -Elementary 4 function calculator
   STRART.PRG  -String art
   STRNGA.PRG  -String art
   SUNDOG.PRG  -Ad for game called SUNDOG - needs SUNDEMO.DAT
   SUMDEMO.DAT -For above
   SUPERBOX.PRG-Pretty color patterns on screen (lo-res)
   SURFAC.PRG  -
   TITLE.PRG   -Pretty, symmetrical pictures.  Set res to low
   VALD414.TOS -Inc. CAD tool.  Use c(ircle), e(llipse), r(ect.) keys, mouse
   VIPSOUND.PRG-Thus Spake Zarathustra - ad for VIP professional
   512COLOR.PRG-See 512 colors on the screen at the same time

Games:

   MGRD.PRG    -Spaceship moves, shoots asteroids and other spaceships
   MEGAROID.RSC-Resource file for above
   HISCORE     -Goes with above
   MASTERMIND  -ST version of famous game - well done (in BASIC)
   TARGET.TOS  -Two cities try to destroy each other - control projectiles
   JOURNEY.BAS -Low level ADVENTURE style game
   LIFE.TOS    -Famous game
   LIFE2.TOS   -Another variant
   LIFE.DOC    -Documentation for the game of LIFE
   BACKGM.BAS  -Game of Backgammon against the computer
   OTHELLO.BAS -Game of Othello either against computer or second player
   CRIBBAGE.BAS-Game of Cribbage against the computer
   4SCORE.PRG  -Game of Fourscore - computer can be beaten
   MAZEMKER.PRG-Produces mazes for your printer - then you find path
   ELIZA.TOS   -Clone (not quite) of famous piece of AI work

Recently someone posted an article summarizing the commands of a pubilc
domain version of micro emacs for the ST. Where was the binary and or
source for micro emacs posted? I would dearly like a copy if some poor
soul could email me one or give me pointers on how to obtain a copy.
I also be willing to mail a disk and money to cover postage and handling.
(or is this the micro emacs that comes with the development system? and is
in PD). Thanks for your replies.
     I am working on a copy of a pretty printer for Modula 2 (converts
source files into a "more readable" form) that i will post if there is
interest.
     By the way, thanks for all who responded with my request for xlisp.
I received two copies, and have proceeded to distribute xlisp to various
ST fans here in Vancouver.

Sorry I forgot something,

you need also buffers for Side 0 Select.

Drive 0 Select, Drive 1 Select and Side 0 Select are directly

controlled by the Sound Chip YM 2149. Play save and use buffers

when using non-ATARI drives.

~~~~~~~~~~~~~~~~~~~~~~~\ lineater, \~~~~~~~~~~~~~~~~~~~~~~~~~
here is the shar file for the 68k disassembler, as i said before it
was written on an Unisoft port of unix and uses b.out.h to discribe
the format of the executable file; for the obvious reasons i can not
include the file here.

remember to cut my .signature at the end of this file before saving
as a shar file

This is the 68000 disassembler mentioned on the net.
It is not my final version by any means, but I have found it extremely
useful and it represents severl weeks' work.

     John Collins.

You should get the following files:

     doc   - MM macros
     makefile

```
     unc.h
     alloc.c
     file.c
     heur.c
     iset.c
     libmtch.c
     main.c
     prin.c
     robj.c

To extract /bin/sh the remainder of the file after the next line
------------------------------cut here------------------------------

# To unbundle, sh this file
echo doc 1>&2
sed 's/.//' >doc <<'//GO.SYSIN DD doc'
-.\"/*%  nroff -cm -rL72 %|epson|spr -f plain.a -h uncdoc -w
-.nr Hb 7
-.nr Hs 3
-.ds HF 3 3 3 3 3 3 3
-.nr Hu 5
-.nr Hc 1
-.SA 1
-.PH "''A Disassembler''"
-.PF "'Issue %I%'- Page \\\\nP -'%G%'"
-.H 1 "Introduction"
-This document describes the first release of a disassembler for UNIX
-executable files.
-The key features are:
-.AL
-.LI
-For object files the output can be assembled to generate the same
-object module, (apart from minor variations in symbol table ordering) as the
-input.
-.LI
-For stripped executable files object modules and libraries may be scanned,
-modules in the main input identified and the appropriate names automatically
-inserted into the output.
-.LI
-An option is available to convert most non-global names into local symbols,
-which cuts down the symbols in the generated assembler file.
-.LI
-The disassembler copes reasonably with modules merged with the
-.B "-r"
-option to
-.B "ld" ,
-generating a warning message as to the number of modules involved.
-.LE
-.P
-At present this is available for certain Motorola 68000 ports of UNIX
-System III and System V. Dependencies on
-.AL a
-.LI
```

-Instruction set.
-.LI
-Object module format.
-.LI
-Library module format.
-.LI
-Assembler output format.
-.LE
-.P
-are hopefully sufficiently localised to make the product useful as a
-basis for other disassemblers for other versions of UNIX.
-.P
-The product is thus distributed in source form at present.
-.H 1 "Use"
-The disassembler is run by entering:
-.DS I
-unc mainfile lib1 lib2 ...
-.DE
-.P
-The first named file is the file to be disassembled, which should be
-a single file, either an object module, a (possibly stripped) executable
-file, or a library member. Library members are designated using a
-parenthesis notation, thus:
-.DS I
-unc '/lib/libc.a(printf.o)'
-.DE
-.P
-It is usually necessary to escape the arguments in this case to prevent
-misinterpretation by the shell. Libraries in standard places such as
-.I "/lib"
-and
-.I "/usr/lib"
-may be specified in the same way as to
-.B "ld" ,
-thus
-.DS I
-unc '-lc(printf.o)'
-unc '-lcurses(wmove.o)'
-.DE
-.P
-As an additional facility, the list of directories searched for
-libraries may be varied by setting the environment variable
-.B "LDPATH" ,
-which is interpreted similarly to the shell
-.B "PATH"
-variable, and of course defaults to
-.DS I
-LDPATH=/lib:/usr/lib
-.DE
-.P
-As a further facility, the insertion of
-.B "lib"
-before and

```
-.B ".a"
-after the argument may be suppressed by using a capital
-.B "-L"
-argument, thus to print out the assembler for
-.I "/lib/crt0.o" ,
-then the command
-.DS I
-unc -Lcrt0.o
-.DE
-.P
-should have the desired effect.
-.P
-Second and subsequent file arguments are only referenced for stripped
-executable files, and may consist of single object files and library
-members, using the same syntax as before, or whole libraries of object
-files, thus:
-.DS I
-unc strippedfile -Lcrt0.o -lcurses -ltermcap '-lm(sqrt.o)' -lc
-.DE
-.P
-It is advisable to make some effort to put the libraries to be searched
-in the order in which they were originally loaded. This is because the
-search for each module starts where the previously matched module ended.
-However, no harm is done if this rule is not adhered to apart from
-increased execution time except in the rare cases where the disassembler
-is confused by object modules which are very nearly similar.
-.H 1 "Additional options"
-The following options are available to modify the behaviour of the
-disassembler.
-.VL 15 2
-.LI "-o file"
-Causes output to be sent to the specified file instead of the standard
-output.
-.LI "-t prefix"
-Causes temporary files to be created with the given prefix. The default
-prefix is
-.B "split" ,
-thus causing two temporary files to be created with this prefix in the
-current directory. If it is desired, for example, to create the files as
-.B "/tmp/xx*" ,
-then the argument
-.B "-t /tmp/xx"
-should be given. Note that the temporary files may be very large as a
-complete map of the text and data segments is generated.
-.LI "-a"
-Suppresses the generation of non-global absolute symbols from the
-output. This saves output from C compilations without any obvious
-problems, but the symbols are by default included in the name of
-producing as nearly identical output as possible to the original source.
-.LI "-s"
-Causes an additional scan to take place where all possible labels are
-replaced by local symbols. The local symbols are inserted in strictly
-ascending order, starting at 1.
```

```
-.LI "-v"
-Causes a blow-by-blow account of activities to be output on the standard
-error.
-.LE
-.H 1 "Diagnostics etc"
-Truncated or garbled object and library files usually cause processing
-to stop with an explanatory message.
-.P
-The only other kinds of message are some passing warnings concerning
-obscure constructs not handled, such as the relocation of byte fields,
-or the relocation of overlapping fields. Occasionally a message
-.DS I
-Library clash: message
-.DE
-.P
-may appear and processing cease. This message is found where at a late
-stage in processing libraries, the program discovers that due to the
-extreme similarity of two or more library members, it has come to the
-wrong conclusion about which one to use. The remedy here is to spell out
-to the program which members to take in which order.
-.H 1 "Future development"
-In the future it is hoped to devise ways of making the disassembler
-independent of all the above-mentioned version dependencies, by first
-reading a files defining these things. This will probably be applied
-after the Common Object Format becomes more standard.
-.P
-In the long term it would be desirable and useful to enhance the product
-to produce compilable C in addition to assemblable assembler. Stages in
-the process are seen as follows:
-.AL
-.LI
-Better identification of basic blocks in the code. Switch statements are
-a major problem here, as are constant data held in the text segment.
-.LI
-Marrying of data to the corresponding text. It is in various places hard
-to divorce static references "on the fly" (e.g. strings, and switch
-lists in some implementations) from static at the head of a module. This
-is part of the problem of identifying basic blocks.
-.LI
-Compilation of header files to work out structure references within the
-text. At this stage some interaction may be needed.
-.LE
-.P
-Meanwhile the product is one which is a useful tool to the author in its
-present form. Comments and suggestions as to the most practical method
-of improving the product in the ways suggested or in other ways would be
-gratefully considered.

I've scanned the past few megabytes of mail on the ST but haven't seen someone
address one of my questions.

I understand the DIN plug outputs an analog RGB signal. Are there TV/Monitors
out that can be fed this signal (modulo connector changes) and give an image
approximately as good as the Atari monitor's?

(I'm in the market for the 1040ST and also for a good TV. Maybe I can save
some $300 by merging the two...)

I have a lot of files that I would like to download to my ST.
Does anybody know if the "fixed" ar68 is compatible with the
unix ar? I would like to archive a source library, download it
and then extract it using ar68. Thanks for any info.

Possibly due to my error and possibly due to network addressing quirks
several new additions to the lsit cannot be addressed. If anyone knows
a working path to either of the following hosts will they please inform

me.

Heaven forbid anyone needs to get their 520ST repaired. Mine has
been in the shop since January 16th and all I get is excuses as
to why I'm not getting it back.

If this is the type of repair service Atari is going to provide,
its reputation is going to go down hill very rapidly!

For the last month and a half I've been told "You'll have it next
week", but next week comes but the computer doesn't.

Since my power supply caused the failure, and the damage might
be extensive, maybe there is no expertise in the service center
and they are stalling because they CAN'T get it working.
On the other hand, maybe parts are not available.
Either way, the service absolutely STINKS!!!!!!!

Why the heck can't someone in the repair organization have some
honesty and tell the truth as to what is happening? What are
they hiding? Why do they have to lie week after week?

Who knows!!

Whatever, I hope to get the computer back some time in the near future.
If not, I'll probably have to take these people court just to get back

a computer. I sure hope it doesn't happen to you.

I read the March Byte article on the 1040ST and resulting info-atari16 questions on the future inclusion of a graphics processor with great interest. From the comments made by Shiraz Shivji in the Byte interview and other Atari personnel on info-atari16, I get the impression that we are in for a spate of Atari machines based on the origonal 520ST architecture but incorporating ram and peripheral improvements, built-in and add-on, ad nauseum.

The thing that worries me about this is that with all these models stretching into the future how compatible will they all be? How will the software houses write their programs if the target machines are constantly changing. There are now two STs (all within a few months) on the market with at least one (with more ram) and/or another (with graphics co-processor) machine(s) in the wings (that's what Atari have told us about anyway). I believe in progress sure, but every time I go to order an ST there is talk/rumour of a new model, (Yes I have not purchased an ST yet!).

I am very keen to get my hands on an ST, I would love to get into some real graphics work, but cannot see myself lashing out a hefty $1000 +/- $100 without knowing if I will be able to use the machine for at least a few months before a new improved/updated model appears. Possibly others out there feel the way I do, I gather from some of the info-atari16 mail that I am not alone?? Maybe Atari would tell us how many models the ST family will have by the end of '86? Orders of magnitude will do!

Until the whole business stabilizes, just a little, or Atari can convince me it will slow down on the rate of new machine releases, I will hold off and continue to use my old faithfull Z80 machine.

Norbert Burman

Would-be ST User.

I don't think the DRI C supplied with the dev kit is slow - in fact it may
be the fastest game in town. I estimate that it is at least 3 times faster
than OSS Pascal based on running some simple fibonacci programs (actually,
the fibonacci result difference was greater than 3 times - but to be
conservative I used the factor 3). However, the time to compile is long and
compiling is awkward (as supplied by Atari). One quickly learns, however to
overcome these defects: Get TOS in ROM, upgrade to 1MEG and install a 650K
RAMDISK - then pare down the libraries a bit, create the appropriate batch
files, put everything into the RAMDISK and go to town. There is one serious
defect with the DRI C compiler, however: some C like functions (e.g. fgetc..)
do not work the way they are supposed to. So, for example, i/o is done a bit
differently with DRI C than with other C variants. My colleague next door has
begun taking the drastic step of changing many of these functions so they look
like C functions.

One other comment: the dev kit has indeed lost its value - the reason is that
almost everything in it is now in the Public Domain in one form or another
(except, perhaps, the Compiler (Gee - I wonder why?)). It was a bargain when
it was first introduced, though.

One more thing - I have found that the people at atari bend over backwards
to help you whether or not you are a developer. Most people do not have this
impression, though. The reason, I think, is that Atari is a "small" company
doing big business and many of us have fallen through the cracks from time to
time just because they don't have the personell to take care of everthing.
I think that neil and dyer coming to the net are an example of this: it took
them a long time to make it to the net (exasperating many of us) but they
did make it and are now doing a very fine job of keeping us informed and
giving individual help when asked (I had a few special favors to ask and these
were granted before I knew what happened - I am too ashamed to tell you what
those favors were because they involved privileges that almost no one else
has at this time).

disclaimer: I have fallen through the cracks many times myself, yet I have
   great respect for the people at Atari (like neil and dyer and frick) who
   have always answered my questions WITHOUT first asking whether I was
   a developer. Above all, I love my ST and I could tolerate a whole lot
   more mistreatment before even entertaining the thought of giving it up.
   I am not connected with Atari in any way.

A word of caution to those of you considering on upgrading your
Atari 520ST to 1 meg.

!!!!!!!!USE CMOS RAM CHIPS ONLY!!!!!!!!!

41256C-15 BY NEC are a good choice

The problem is that a non cmos ram chip can draw as much as
70 ma of current. Therefore 70*16 equals aprox 1 amp of current!

Summary:

By the way, there was a slight bug in the Ramdisk source that I posted
(by mistake as I was trying to REPLY to a message that seems to have
come from some mailing list...) to this newsgroup a little while ago.

The 'cnt' variable gets set to 92165. That value should have been

```
cnt = 92160;
```

Otherwise, too much memory gets cleared! Sorry for any problems this may
have caused.

welcome to the club, i also recieved such a foul mouthed missive
from mrc; i was advised by people that i work with that know him
that he is a child and best ignored. I was also told that when he
left his last job to come out here, his old boss called his new one
to thank him, i don't know if that is true but after one email from
him i believe it. As my wife says consider the source and ignore him.

(Does something still eat this line? Rn doesn't.)

It sounds like either a thermal problem in the high voltage focus (is
the de-focus all over the crt screen) or posibally (but less likely) a
thermal problem in the crt gun structure itself. The only way to determine
if I'm right would be to disassemble the monitor and play with the focus
pot while it is warming up, or use cold spray on it after it is warm.
It is not likely to get better but may stay that way for years. If you
can do without it for a while, send it back. You payed to have it perfect!
Mine is OK but note that since it works at 70 Hertz, and everything around
it is 60 Hertz, it is very subseptible to magnetic field interaction. You
will know when the picture starts moving or waving at you. I can't have
the color monitor on (but unused) and next to the B/W (12 inches) while I am
using the B/W. Also, keep the power blocks (transformers) away from the
monitor -- especially the back. Move them around the monitor with it on to
see what I mean.
     Good luck.
     Ken Adam

Be carefule here. I'm not sure about TOS, but GEMDOS has this misfeature
that keeps a an FCB-like data structure in memory for every directory node
visited so far. The original intent here was to speed up future references
to files in that directories subtree. The patch you recommend will eat up
a lot of TPA space very fast! (Is this true for TOS, Landon?)

Atari did not completly write TOS. They did modify GEMDOS to suit their
needs. It has a slightly different set of rules for interfacing with
the BDOS and the BIOS. But it is mostly GEMDOS.

GEMDOS was a complete write of an OS done in a very short period of time
based on some prototypes we had working here at Dig. IT is NOT CP/M anything.
It was built as a DOS emulator for the GEM system so we could get it working
on 68k systems.

     I use uudecode all the time (the one posted about November with
atari ifdefs), and have had no problem with any uuencoded programs, both
with and without the ROM TOS.

Nf-ID: #N:iuvax:54600018:000:6794
Nf-From: iuvax!franco   Mar 8 16:04:00 1986

Here is a UUDECODER for the ST which I tested myself on the RTXDEMO binary
that was posted recently. This works for me and it should work for you.
Please try it and report results to the net. It is written in dev kit C.
Link with osbind, gemlib, libf. Soon to come - the encoder.

Hopefully there will be no more complaints about uudecode inability after
this.

```
/*
 * Uudecode -- decode a uuencoded file back to binary form.
 *
 * Useage: (CLI) uudec <uuencoded filename>
```

```
 *         (GEM) click on uudec.ttp
 *               enter <uuncoded filename> in dialog box
 *               hit CR
 *
 * Result: File specified in first line of uuencoded file is created,
 *         contents of uuencoded file are decoded and placed into
 *         the created file.
 *
 * How it works:
 *         The bits of every three consecutive bytes of the binary file are
 *         encoded into four consecutive printable ascii bytes according
 *         to the following diagram:
 *
 *               |         |         |         |         |
 *               |x1x2|3456|x7x8|1234|x5x6|7812|x3x4|5678|
 *               ----------------------------------------
 *
 *         where the long vertical bars separate bytes and the short
 *         vertical bars separate half bytes.  The x'ed bits are not
 *         important to us (they are given values which result in
 *         printable ascii characters).  The first eight digits
 *         increasing in order from 1 to 8 mark the positions of the
 *         first byte of the group of three binary bytes.  The next
 *         eight mark the second byte and so on.  Each line of the
 *         encoded file contains a count character followed a number
 *         (multiple of four) of encoded bytes.  To decode we merely
 *         need to go through the usual bit pushing.
 *
 * Problems: Contact J. Franco (franco@indiana.CSNET)
 *
 * Comment: This should work.  I successfully downloded the recently posted
 *          RTXDEMO with no trouble whatsoever (and that is a pretty big
 *          file).
 *
 * Note:    This is the latest of a number of hacks of a uudecoder originally
 *          intended for the IBM PC. (3/6/86 - JVF)

We had also some trouble in this direction. We have bougth about 30 ST's
and two of them have had the same fault(s). Our dealer told us, that this error
always occurs, when the custom MMU is defective. The same thing I have read
in a ST magazine here in Germany.

.....this line reserved for pacmen

The March issue of Byte Magazine features a piece on the 1040ST, including an interview with Atari's Vice President of Research and Development, Shiraz Shivji. We have received many questions on the "graphics coprocessor" chip that he mentioned in that article. Here is some further clarification, courtesy of Atari Corp. President Sam Tramiel:

The graphics coprocessor that is currently under development is intended for future products in the ST line, _not_ the 1040ST. We expect to release a product containing this chip at a higher price than the current products, and it is expected to be on the market late this year.

For owners of current ST computers, we will make this chip available on an upgrade board, to be available as soon as possible.

I'm interested in the 20Meg Atari hard disk. I had heard rumors to the effect that the developers hard disks have a faster data transfer rate than the soon-to-be-available commercial 20Meg Atari hard disks. I asked about this at my local dealer, but the fellow there told me that the only differences were cosmetic: metal case vs. plastic case. I'm not sure he's got the straight story on data transfer rates, as he was quoting 10Mbits/sec to me. I realize that the DMA controller can transfer at that speed, but I had heard that the hard disk controllers were actually running at 7.5Mbits or 5Mbits.

   I was wondering if anyone had the straight story on the differences between the developers and commercial hard disks. The two topics of

particular interest to me are:

1) Performance: data transfer rates, access times, etc.
2) Fan noise. I seem to be overly sensitive to noise. (I REALLY like the fact that my ST doesn't have a fan, but the hum (60 cycle, it sounds like) from my monochrome monitor begins to bug me at times. My color monitor is silent. Anyone else have a noisy mono monitor, or is it just mine?) Anyway, back to hard disks... the developers hard disk I looked at had a fan that seemed to be about average for fan noise.)

Other differences of more minor interest would include requirements for parking the heads. I understand that the developer's hard disk requires this, but I can't imagine that a commercial version would.

Can anyone at Atari or elsewhere shed some light on this? Thanks.

I have a few questions about ST Basic:

1) How do you get more than 16 colors in Basic?
2) Are there plans for a compiled basic in the forseeable future?
3) I can only get sound channel #1 to work. How do I get the other channels to work?

I suppose all these questions should be prefaced with the more

general question: when is a newer release of the basic expected?

Aloha,

Jonathan Spangler

This is being posted for a friend.. (Sure. That's what they all say.)

Anybody know of typesetters (or incredibly intelligent word processors)
for writing techincal papers (I.E. Equations and other ugly things)
are available for STs?

The KERMIT given with the Development Kit doesn't work with the new

TOS (197kbyte). After starting it from TOS I get a hangup. Even with

the old TOS there are certain problems resulting in a hangup. Did

anybody have the same experience? There is still no public domain

version of KERMIT available. The KERMIT people are still working on

it. By the way, the KERMIT given with the kit looks like a very

old version.

Computer-Viruses: Help needed !!!

Please don`t mind for posting my request into this
notefile.

I have been searching for any kind of literature
concerning the subject of `computer viruses` for
three weeks now and my results are rather poor.

I only found 2 interesting entries in the databases
locally available. Because I intend to get a Ph.D.
in protection mechanisms against computer viruses
I really have a big need for more references and
hints to get.

So, if anybody out there in the net does know something
about the stuff, please give me any kind of information.

I`m also interested in getting contacts to others
working on the same or similar subject.

If there will be enough feedback I will summarize the
replies to the net.

Thanks in advance

Does anybody know how to use the new EPSON LQ800 (24 pin) with
the 520ST in graphics mode (like a screen dump from the OS).
THe LQ800 works fine in text mode, but I get nothing but garbage
when I try to send graphics. The basic problem is that the 24
wire head needs 3 times the information. I know that there is a way
to default the LQ800 to regular FX80 graphics codes but I haven't
figured out how yet. I have tried sending ESC L and ESC Y befor the
dump but this didn't work. I have called EPSON but they don't
seem to know either. How do I know that this is possible? I have
seen it done at a store, but since I didn't buy the ST at this particular
store, they weren't willing to tell me how to do it. Also,
my phone numbers for Atari don't seem to work any more.
Does anyone have a phone number that actually gets answered.
(tape recorders don't count)

Thanks
R.T. Bradstrum

Product: DEGAS
Developer: Batteries Included

Address: 17875 Sky Park North, Suite P, Irvine, CA 92714
Phone: (416) 881-9816
Price: Discounted to $23 (MRSP unknown)

Probably everyone has heard of DEGAS by now and there have been
several reviews in magazines. Frankly, it is $23 (or so) well
spent. The human interface is well designed and it appears to be
quite a capable paint program.

Since I am not an artist, I'm not really qualified to comment on
its suitability for art, but the demo pictures are really quite nice.
It IS, however, a good tool for viewgraph preparation. As a frustrated
typographer, it's fun to create a new font with the font editor and
try it out in a graphic design. I was a little disappointed in the
quality of the fonts provided (I am working on a Futura-like font)
and the 8H x 16V fixed character format is a serious restriction.
The magnify feature is good for touching-up large display text.
The EPSON print driver works OK with our Panasonic 1092 with good
results. (Running the dot matrix output through a Xerox copier
tends to integrating the jaggies and reduces "blockiness.")

DEGAS is easy to learn and has a good user's manual. Give this
one 3.5 stars.

Question and Answer Bulletin February 1986
Copyright (C) 1986 by Atari Corp. "all rights reserved"
1196 Borregas Ave., Sunnyvale, Ca. 94086

Here are the latest questions from the Atari developers mailbag as answered by John Feagans, Director of Software Technology. Leave questions on Compuserve for PIN 70007,1072 or GO PCS57 for Atari developer SIG information.

How can I have a different background color for text. There does not seem to be anything I can set to make this happen.

A way we recommend to make this happen is to do a rectangle fill of the area behind the text then use v_gtext with a transparent writing mode.

I have a GEM application that I am porting from the IBM PC. Everything compiles O.K. but I get a number of undefined symbols in the link step. Some of these symbols are dos_free, dos_gdrive, dos_lseek, and dos_open.

The problem here is some differences in name between what you are using, what is described in the GEMDOS spec, and what is actually in the bindings. Here is a table which may explain what is happening:

Your code	GEM DOS manual	osbind.h
dos_free	d_free	Dfree
dos_gdrive	d_getdrv	Dgetdrv

```
        |dos_lseek      f_seek              Fseek   |
        |dos_open       d_open              Fopen   |
        ------------------------------------------
```

Question and Answer Bulletin

From the VDI there doesn't seem to be a call to set pixels. How do I do it and be compatible with all resolutions?

You can do it by drawing a 1 pixel wide line with a length of 1 pixel. There is also a line-A call for setting pixels. The latter method is much faster, however, it does not clip.

I just installed my ROMs and the system doesn't come up. It is just a white screen. It is like this every time I reset. Oh...there it is...what happened?

If you have just installed your ROMs and do not have a disk drive attached, the TOS is going to spend considerable time attempting to read some files from disk. It is looking for desk accessories, an auto folder which may contain drivers to load, and a desktop.inf file created if you saved a desktop. If you want to shorten the power-up process, then have a disk attached with a valid floppy disk in the drive.

I just ported my IBM PC version and have the symbol UMULDIV undefined.

VDIBIND defines MUL_DIV, mul_div, and umul_div, but the symbol UMUL_DIV is missing. If you are programming in C perhaps you could #define it in a header file. In assembler, you could equate UMUL_DIV to umul_div.

Can I boot another operating system if I have TOS in ROM?

Yes. The system has been designed so that a disk with a boot sector can have another operating system which can be loaded in. Another way to load another system would be to put a driver in the auto folder on the system disk. A third interesting method would be to make a desk accessory which loads the new system. It is also possible for a program to perform an extended bios call PUNTAES which frees up the memory used by the AES and desktop while preserving the bios,dos, and VDI.

How can I load in code from BASIC? Where is it put? How do I allocate space for it?

To use the BLOAD function you must first allocate a string array big enough to hold your code. Next use the varptr function to get the address of the storage area. Use BLOAD with this address and the CALL function to execute your code. One final point--make sure the code is relocatable and completely relative as BLOAD does no fix-ups.

How are the icon outlines dragged on the desktop and what is the shape?

Icons are dragged on the desktop by moving a polyline XOR box. The vertices are a fixed set that resemble the edges of the mask data for the icon.

How do I stop BASIC from drawing windows on my output screen?

Windows are redrawn when BASIC calls a routine in the event library. Some examples of these routines are evnt_multi, evnt_keyboard, and evnt_button. It is possible to stop the evnt_multi calls because there is a BASIC system table called SYSTAB. Check the documentation for particulars. At an offset of +24 there is a variable called GEMFLAG. A POKE of 1 in this location turns the event calls off and a POKE 0 turns the event calls on.

When I double click on AS68 from the desktop, the screen turns white and immediately returns to the desktop. How do I type in the name of the file to assemble?

It is posible to run AS68 from the desktop. The procedure is to install it as a TTP type, (TOS takes parameters) and save desktop, or show-info and rename it as a .TTP. Next time you double click on AS68, a dialog box for parameters will come up. You can then type "-u -l myfile.s" and click on OK to run the program. Object files fill be generated and control returns to the desktop upon completion of the assembly.

I have a program where I am drawing my own dialog boxes and menu by constructing the object tree and calling OBJC_DRAW. The problem is that when I draw the dialog box, the menu pops down. I have tried everything to prevent this. What is happening?

We suspect what is happening here is that you may be passing the address of the menu rather than the dialog box. If you have the level set to MAXDEPTH, everything including the dialog box over a popped down menu may be drawn. Double check what you are passing to the objc_draw.

I have a dialog box with an editable field. When I try to put string to initialize the data, everything is messed up. It seems like the pe_text pointer is pointing to the wrong place!

The OBSPEC field of the editable object points to a TEDINFO structure. In this structure there are three pointers: in order they are 1) to a string containing the actual text, 2) to the template, and 3) to a character validation field. Beyond getting the proper pointer, another problem you may encounter is that the string is a fixed length. You may be moving data into it which is longer than was created at the time you defined the text in the resource construction set.

I am running the batch program and get a bus error after c0.prg has been running a little while compiling my program. Could this be a bug in the compiler.

A bug is always possible but here are a few other things to suspect when a problem like this occurs. The batch program will abend if it cannot find a specified program to load. You may also have an include file with something illegal. That might explain why things proceed through the pre-processor in abort in the first compile step. Another thing to check is if you are running out of space on the disk from which the compiler is running. Each step of the compile creates some intermediate files which require space. It is possible to specify to the compiler which drive to which it writes the intermediate files.

I am transferring files from my IBM PC to the ST using kermit. ASCII files come over o.k. but binary files are messed up.

When you transfer binary files you must tell the server to SET FILE TYPE BIN. You must also tell kermit on the ST to gi (get image) or si (send image).

I am using ICED.PRG to design my icons for use in my resource file. How do I load these icons into the RCS?

As an example, let us consider that you are in the RCS and have created a dialog box. Drag the icon type from the parts box into your work area. Select the work area and select the icon you have just moved down. Bring down the menu under the file heading and select the open. At this point the open item will not load a new resource but will load in and link the data for the icon file you select in the file selector.

What documentation errors do you know about in the Hitchhiker's Guide to the BIOS?

The current Hitchhiker's Guide shows the initial PC being set from $FC0000 and the initial SP from $FC0004. These values are reversed.

Hitchhiker's Guide is wrong in two places about the GEMDOS call $20 to set supervisor mode. The flag to merely test the current mode is $1 and not the $FFFFFFFF specified. The latter will crash the system. Second, the returned value from this function is $0 for user mode and $FF for supervisor mode, not $0 and $1 as documented.

To get started writing my program I need some more example programs. Where can I find some?

We recommend that you get onto Compuserve and take a look at the Atari 16-bit SIG and also the Atari developer's SIG. For the latter, type GO PCS57, and read the membership information. We are constantly uploading example programs into the data libraries as well as other developers. These programs are available for download to your system.

I am trying to redirect standard output by using the Fforce function. Gemdos is checking the handle for a number less than 6 and reporting an error. How do I redirect the console?

The new handle which you pass this function must be greater than 6 or less than 0. Values of -1, -2, -3 correspond to CON, AUX and PRN.

How can I make a listing of my assembler program?

There is a way to make AS68 write a listing file to disk. To do this you must add the parameter -P and specify the output file name following the input file name with >filename. Here is an example which may work for you.

```
AS68 -P -L -U file.s >list.txt
```

You can do this either from a batch file or you may install AS68 as a TTP and do this from the desktop.

I am trying to compile the simple example C program that just uses printf to output "hello world". I keep getting undefined symbols during the compile and the object will not link. What is wrong?

The most likely cause of the compile errors is that you are missing the header file STDIO.H. Be sure that at the beginning of your source file that you put the following statement in:

```
#include "stdio.h"
```

Problems with the link may be caused by not specifying all the files that are required, or placing the files in the correct order. Here is the bare minimum you should have for a C program that is not a GEM application:

```
gemstart.o,(your object),gemlib,libf
```

Why is the return key not returned by the getchar function?

When Digital Research wrote the 68k run time libraries for the Alcyon C compiler they used the Unix new line definition for terminating input. In a generic system the return key would generate the sequence CR LF. The run time libraries throw away the CR and count on the LF coming through. The only way to get around this problem is to use the unfiltered bios or dos input from console. The scanf function is similarly afflicted. Instead of forcing the user to terminate input with control-J, build a buffer of characters terminated by a null character using the bios and bdos. Pass

this string to sscanf which acts only on the string and does no keyboard input.

I just read in the March issue of Analog that the OS/9 operating system *is* being adapted to run on the ST. They didn't mention the name of the company though. Also they reinforce my opinion that almost all of the software HIPPO puts out is rushed and that you should check out your other options before buying their inferior software :-)> (This opinion doesn't apply to their hardware, as I have no information on it).

I have been looking (for about a month) for a public domain
full screen editor for the ST. I have tried both local
ST groups, and calling BBSs in different parts of the country.

Can anybody (especially the Atari-guy) point me in the right
direction, or is it to early yet for anyone to have designed
a public domain editor? (Something akin to PC-WRITE for the
IBMs would be great...)

Thanks in advance...

[]
After waiting over three months for my basic from Atari, I finally
received it. Either the manual is incorrect or maybe I'm thick
but I can't get some of the functions to work as described in the
manual. I would appreciate any help...

1) inp()   function is supposed to read from the keyboard single
     characters. I tried inp(-4) to read the status and it only
     returns 16. Try inp(4) which also returns 16. Anybody know
     how this works?
2) wave()   function for producing sound. Manual page is missing the
     table for envelope shape. Would like a complete explaination.
3) buf graphics   what is this? I didn't understand it's use.
4) large files   If you try to load in a very large basic program
     the 520 will load the file from the disk in one large piece,
     then several small pieces. It tells you of no errors.
     The real magic is it will give you all sorts of undefined
     errors, none of which are out of memory errors.

Thanks in advance for any help with the above problems. As I have a

manual I am willing to help others without, just send me which functions
you would like descriptions of.

I don't get access to the US Atari mags (sniff sniff boo hoo), so any
continued information on if/when/whether OS/9 will be available is
always nice.

What I did get two days ago is an offer of the Lattice C-compiler.
Has anyone any experience on whether this is better than the Hippo one?
I have seen the Whetstone figures for the Atari, but do not know which
compiler they used.

Has anybody tried porting GNU Emacs to the ST? It ought to run fine
in a meg machine, unless the C compiler and environment are too far
off from Unix. (Of course, you'd need a hard disk to compile it,
since the source is about 8 megs -- and even the executable image
might not fit on a floppy.).

>PS: This assumes that the spec sheet is correct.

     Here's a simple test for checking whether a monitor is interlaced:
First you display a blank screen - i.e. all white. And you wave your finger

in front of it. Do it fast enough to make 8 images of your finger appear on the screen. Now get a stop watch and time 40 waves of your finger - i.e. 640 images of your finger altogether. I did this and obtained 640 images in 8.96 seconds. This gives 71.43 Hz as the image frequency. I know this is just luck that it is so close, but an accuracy of only about 20% is necessary here.

Second, you display only every odd or even line, which should give a frequency of half as much for interlaced, or the same for non-interlaced. I just tried the same test on the GEM desktop dither pattern and got 70.80 Hz. This is not surprising, because the dither pattern uses all lines.

Could some good person please do the experiment for alternate lines only. I haven't got my second disk drive in the mail yet. So I can't be bothered to write a C program for it.

Alan Kennington.

It is true that in comparison to a lot of the poorly written stuff on the market for the ST, Degas is refreshingly usable. (Unlike the revolting terminal "emulator" I sometimes use.) But in spite of all the good things said and written about Degas, a perusal of the VDI and AES manuals will reveal that the author(s) simply made rational use of existing program components. There seem to me to be few innovations in Degas. The idea of using the left mouse button to flip between a control window and the worksurface is a very

nice way of doubling the effective screen area. But the actual operations selectable from the control panel are almost entirely selected from the repertoire provided in the OS.

If congratulations are in order for Degas, they are equally appropriate for the designers of VDI/AES who have written in many Mac-like painting routines, and even a resource creation and icon editing facility, so that the design of a control panel is a positive pleasure. If you haven't created a set of control panels, menus, alerts and dialogs with the development kit yet, you really should deny yourself the pleasure no more. And all the fuss over the manuals being slightly difficult to read is beyond my comprehension. The only really painful thing is trying to use the routines from C with only one disk drive. And I certainly don't want to find out how to use VDI/AES from Basic. Any good feeling I might have had towards this "language" have evaporated as a result of the nasty little 130K patience-tester that Atari were unwise enough to try to pass off as a Basic interpreter. But I think Basic will be okay as soon as they get a team of experts to rewrite it.

Sorry I can't think of anything good to say.

So long, Alan Kennington.

<Mmmm, tasty>

I've just started using my 520ST for things other than terminal emulation, and I have a few questions for anyone who may be able to help me. I have the developers kit, but not much else.

1) Does anyone know how to convince the Control Panel not to nuke the time? I wrote a program to put in my "auto" directory to set the time. It works fine normally, but when run from "auto" it apparently sets the time, only to have it overwritten by the control panel accessory at startup. Any suggestions??

2) Can a desk accessory be written such that it runs to completion,
   and simply terminates (As opposed to sitting around in an infinite
   loop of sleep calls)? Specifically, I have in mind writing an
   accessory to run through an 'auto2' directory, and run stuff
   AFTER all the desktop information is set up.

3) Has anyone got a copy of a public domain RAMDISK that works?
   The person who gave me mine mentioned that there was a bug, but
   I never saw any fixes come by.

4) Has anyone gotten RTS/CTS handshaking to work well? I have my ST
   hooked directly to a UN*X box at 9600 baud, and RTS/CTS doesn't
   work at all. I'm not positive it's the ST's fault, so I'm just
   looking for verification.

RE:
> I have been looking (for about a month) for a public domain
> full screen editor for the ST.
>>Has anybody tried porting GNU Emacs to the ST?

There is a program called Micro Emacs that has been ported to the Amiga.
I believe it originally ran on the IBM. It may not be too hard to move
it to the Atari.

I think the binary is about 40KB on the Amiga and it does NOT require
a hard disk to compile. There is no Mlisp. Changing key definitions

requires recompiling one of the routines.

Also, someone recently posted a VI like editor to net.sources.
(or was it mod.sources?)

Does anyone (specifically at Atari) know whether there is going to
be a place on the 1040's pc board for the Blit-coprocessor? Will
people who buy the first rev of the 1040 be able to upgrade?
(for people who have not heard of the Blit-chip see March Byte)
thanks in advance...

<<>>

  This is just a subtle warning to all of those interested in upgrading their Atari 520ST's to 1Meg. I attempted to do so two weekends ago and the result was a non-functional 520ST and about 24 hrs. of wasted time.
  Now there will be those out there that will say that I might have used a wood burning gun instead of a nice soldering iron, but that is not the case. I am getting my Ph.D in EE and have worked as a tech. for many a summer. I have performed similiar upgrades to H-19's and Radio Shack Color Computers (piggy-backing chips and the like). This upgrade is NOT a simple one. It is not due to the fact that the techniques are that difficult, just that the component values are VERY touchy.
  For instance, I tried BOTH the resistor and non-resistor upgrades - neither worked. I have seen (since I tried my upgrade) about the fact that the values of the resistors are sensitive to the manufacturer of the 256K DRAM chip. This is not my idea of a good, safe upgrade.
  My only warning is this, DO NOT try this if your 520ST is AT ALL as valuable to you as mine is to me (doing without it for 2 wks. was very tough). If you have the time and the persistance to MAKE it work then you might want to try it. If possible, find out EXACTLY what combination of components worked for someone else (any offers out there?).
  I am not trying to bad-mouth anyone, only trying to save someone like myself a LOT of grief.

                    Bob

<<<<<<< line eater >>>>>>>

Couple of questions:

1) Several people have mentioned "auto folder", and being able to run
   a program automatically at startup. The manual that came with my 520
   doesn't mention any thing about being able to do that. How do you put
   something into the "auto folder" and where can I find some info about it?

2) I've gotten a couple TOS error messages when trying to run some programs.
   The message pops up in a box, with a stop sign in it, and gives an error
   number (eg TOS error #35). How can I find what that error number means?
   I have the Abacus "Internals" and "GEM" books and couldn't find it there.

There was a guy from Haba at our last AUG meeting showing us the Haba hard
disk (10 meg) and some of the Haba software. The disk looked nice, and
should be shipping in a week or two. He hinted at being able to upgrade it
to 20 meg but made no commitment as to when and how much. He said they are
no longer selling the Hippo C, but will continue to support it. They are
working on a more powerfull C compiler (no hint as to when it will be out).

I strongly urge anyone interested in performing the 1MEG upgrade to disregard the previous note. I know of over a dozen Upgrades that worked either right away or soon after (after backtracking and discovering a wiring or some other mistake). The only Upgrade that I know of that resulted in permanent damage is the case of the previous author. I personally found the upgrade to be a relatively simple procedure. Furthermore, I cannot agree that components are all that sensitive - you can heat the DRAMs pretty well before they give out, for example. The one thing the DRAMs are sensitive to is static electricity. If you observe simple precautions against static buildup (aluminum foil on the table and in contact with everything as often as possible) they will not be damaged. Period. Another thing that might cause a problem is powering up a DRAM which is only partially connected (there is a very effective, simple precaution to observe here as well - namely, do not power up until the connections are complete). Also, I have NEVER EVER EVER even attempted an upgrade of any machine before. Also, I have NEVER EVER EVER even looked inside of a computer before. Yet my upgrade has been working for three months now.

Notice that I am suggesting that people disregard the previous note and I am not saying whether the author is right or wrong. For all I know the author may be right (but I am pretty sure he his wrong). The reason I am suggesting that the note be disregarded is that absolutely, positively no meaningful information whatsoever was presented to support the conclusion made. I bring this up because this sort of thing seems to happen more than half the time on the net. Please, Please, Please, people. If you are going to make a statement that may strongly affect how others will use their machine, post the deductive path used to come to the conclusions you make!!! Remember, you are not talking to your friend down the block - you are talking to perhaps tens of thousands of people. Be responsible! Please.

To: John Zuschlag (I6191008@DBSTU1.BITNET)

Subject: CP/M86k vs. TOS

John,

   Forgive me, but upon discussing your comment about TOS -not- being CP/M68k to a friend of mine, he thinks you are incorrect. Since he is also fairly well informed about the ST, and in touch with many key people, I thought it would be best to ask you on what "authority" do you state the "facts" that CP/M68k is not in the ST, and what facts do you have to substantiate this beyond any reasonable doubt, such that I can give this information to him and he can research it himself to his own satisfaction.

    Thanks for your help and sorry about making you "prove" yourself, but obviously the difference between having CP/M68k as a central core and their own OS is a pretty major issue so it will be good to have the truth cast in gold before it gets twisted around.

I've had pretty good luck in speeding up the compile-link time by using a 285K RAM disk. A RAM disk of that size is possible when you have TOS in ROM, but no 1Meg upgrade. My total compile-link time went from 8minutes to 2:30 minutes, by telling the compiler, assembler and linker to use C: for temporary files, putting the libraries on C:, plus a few other small files. It took me quite some time to figure out how to do this, but it was worth it. Of course, once I get my 1Meg upgrade I'll put everything into RAM disk, and I expect the compile-link time will go down even more.

Have any of you had similar experiences? I'll post my batch files, plus a list of the files in RAM disk, if there is interest.

I just spoke with aa Atari retailer in Indianapolis that is offering some pretty good prices on ST stuff. For Example:

1. A 520ST, Single Sided Drive, Color Monitor for $800.00
   Check or Cach Price (add 5% for Credit Card, add 5% for tax within IN)
   The price includes only the software that comes with the particular machine you buy. If you want all free software that Atari will eventually make available (NEOCHROME, STBASIC, LOGO, STWRITER) you should also include about four disks and $20 copy charge or $50 for a package of disks

   some of which will be used to copy the above onto (you keep all ten
   disks).

2. If you buy the above you may purchase VIP for an additional $125.00

3. If you buy the ST above you may purchase a second, double sided drive
   for $250.00

If interested give a call to Pat McGraw at 317-291-8882 or write

       Pat McGraw
       Microcomputers Inc.
       3350 N. High School Rd.
       Indianapolis, IN 46224

I have no connection with Microcomputers Inc. I have never even been there.
However, a friend of mine has been there so we know the place exists. I
cannot say anything about the service one might expect from this
organization. However, Pat was easy to talk to on the phone, seemed helpful
and WANTS to sell computers. What the heck.

   Recently someone posted a letter they had recieved from Electronic
Arts - a computer game company - in which EA stated they had no intentions
of developing new (or old) games for the Atari ST or the Atari 8-Bit line.
The reasons given were that basicaly the ST was crap and that no one owned
an 8-Bitter.
   A number of people complained about this to both EA and to Antic and
ANALOG magazines, and both of these mags suggested a letter campaign to inform

EA of it's error. Well in the April `86 issue of Antic you will find this letter:

> The response of your readers to Antic editorials is growing. We have recieved quite a few letters, and because of the interest shown by Atari users, we are planning the following hit products for the Atari 800 in 1986:
>
> Adventure Construction Set
> Heart of Africa
> Mail Order Monsters
> Marble Madness
> Racing Destruction Set
> Skyfox
> Software Golden Oldies (Software Country)
> Ultima IV (Origin Systems)
>
> We hope to see at retail the kind of response we have seen in our mailbox!
>
> Trip Hawkins
> President
> Electronic Arts

So now that we've gotten EA to admit it's error let's make sure that they realize that their change of mind is justified. Also, if every EA purchase was accompanied by a letter of appreciation and a brief ps on how nice this game would look on an ST we may be able to get the ball rolling in that area as well. In the meantime, don't you ST owners give up! If EA can admit it's mistake for the 8-Bit line it's only a matter of time as far as the ST is concerned.

I upgraded my ST months ago and it worked first time. I used NEC 41256-15
DRAMs (*exactly* the same part as my Atari installed DRAMs, but manufactured
five weeks later!)

I did not install resistors, and I'm not sure if I will. I do not have
the ROM upgrade yet. One poster to the net said installing ROMs fried
his resistor-less upgrade, but others said it worked fine without resistors.

If the damn resistors are so important, why didn't Atari install them
on the lower 512K bank?

unless the ST does things a lot different than other computers i've seen
your description to Mike K. was inadaquate. Direct Memory Access still
requires use of the address and data paths, the advantage is that this may
be done without processor intervention, except bus arbitration, during times
when the CPU is occupied with decoding or executing an instruction. Unless
the ST has some sort of dual port access a-la-shared memory, the DMA port
represents no gain over direct bus connection.

[Note: if this is getting to any 8bit groups it isn't my fault.
I am mailing this to info-atari16@su-score on the ARPA net]

Here is a batch file which I use for running the compiler and linker
using a 285K RAM disk installed as drive C:, with source on drive B:
and the compiler, assembler and linker on drive A:.

```
C:rm C:%1.prg
cp68 -i B: B:%1.c C:%1.i
c068 C:%1.i C:%1.1 C:%1.2 C:%1.3 -f
C:rm C:%1.i
c168 C:%1.1 C:%1.2 C:%1.s
C:rm C:%1.1
C:rm C:%1.2
as68 -l -u -f C: -s C: C:%1.s
link68 [temp [C:],u] C:%1.68k = C:gemstart,C:osbind,C:%1,C:vdibind,C:gemlib
relmod C:%1
C:rm C:%1.68K
C:wait
```

The argument %1 is the name of the single program to be compiled and linked.
Additional required libraries can be added beyond 80 columns in the link68
line, or you might want to use the com option as described in the
documentation.

The philosophy behind this setup is to put all files that will be *written*
into RAM disk, since writing a file takes longer than reading (probably
because there is verification going on). Also, the biggest bottleneck
seems to be the linker. Try replacing C:gemlib by B:gemlib, for instance,
and watch that drive spin for an additional 30 seconds or so.

Oh, by the way. The batch file, and all files without a C: should sit
on the same drive (I use A:). Also you need the file C:as68sym.dat (I
think that's the name) to initialize the assembler. I have all my
source code, .h's and the editor on drive B:.

Please let me know of your experiences with this, or any improvements, or
comments.

>   characters. I tried inp(-4) to read the status and it only
>   returns 16. Try inp(4) which also returns 16. Anybody know
>   how this works?

The manual is in error -- use INP(2) and INP(-2). Using SYSTAB to turn off
GEM will make this work very well.

> 2) wave()   function for producing sound. Manual page is missing the
>   table for envelope shape. Would like a complete explaination.

WAVE a,b,c,d,e
 a=voice to enable. 1 is the default (which is why the SOUND command only
   uses 1 voice normally. Add 2 to use voice 2, add 4 to use voice 3. Add 8
   to use noise on voice 1, 16 for noise on 2, 32 for noise on 3.

 b=envelope enable, to use the programmable envelope instead of pure tone.
   Add 1 for voice 1, 2 for voice 2, 4 for voice 3.

 c=which envelope to use.
         0-3= ________

        4-7= /|_______

     8=   \|\|\|\|\|

     9=   _________

     10= \/\/\/\/\/

```
     11=    ________
           \|

     12=   /|/|/|/|/|

     13=    _________
           /

     14=   /\/\/\/\/\

     15=  /|_________
```

 d=period of envelope. Use large numbers, in hundreds or thousands.

 e=duration of sound before next BASIC command is executed. Usually 0.

NOTE: Best technique seems to be to set WAVE then set SOUND for each voice,
      setting delay>0 only on the _last_ SOUND command.

> 3) buf graphics   what is this? I didn't understand it's use.

This sets up a 32K graphics buffer, so menus and other windows do not
obliterate your graphics.

> 4) large files   If you try to load in a very large basic program
>   the 520 will load the file from the disk in one large piece,

>   The real magic is it will give you all sorts of undefined
>   errors, none of which are out of memory errors.

Are you sure? I never had that problem with my programs. How large is
large?

Tell your friend to look in the developer's kit. There is documentation about GEMDOS in there. It also talks about a few of the differences between GEMDOS and CP/M68K. There is much confusion on this point because the developer's kit also has documentation relating to CP/M68K. This documentation was included because the C compiler and various other tools were originally written to be used with CPM/68K, so the documentation was taken from the CP/M68K manuals instead of being rewritten specifically for GEMDOS. Hopefully this will be remedied in the next release of the developer's kit (which is coming soon!!).

Also tell your friend that programs compiled with the C compiler in the developer's kit must be run through an additional filter called RELMOD that rearranges the file headers from CP/M68K format to GEMDOS format.

Tell him to call Richard Frick at Atari if he still has doubts.
Maybe Richard's answer will convince him.

Terry-

Hmmm, looks like that we've got a problem here...

When the ST was presented to the public all testers told that it is

using an enhanced CPM/68k. They also told that the disks use the IBM

PC format. Actually it's the same, except 2 small differences. If you

add a 5" floppy to the ST you can transfer ONE file at a time (with

more you get problems with the file allocation table) from the PC to

the ST and vice versa. In the 'Hitchhikers Guide to the BIOS' and

in the documentation they compare their system quite much with MS-DOS

(sometimes to often). Actually it is very similar to MS-DOS (not only

Unix; like I told before). The subdirectories are handeled like in

MS-DOS. I never worked with CPM/68k but there was a time when I wanted

to build such a system (was too expensive), so I know at least some

facts about it. Unfortunately I don't have access to my documentations

right now... but I'll dig it out when there is need for it.

(Then I can post a comparison of the system calls.)

In general you push your desired function on the stack and call the

system. And this functions are different in both OS's as I know.

Next: You've got several system components: GEMDOS,BIOS,XBIOS,GEM and a grafics kernel. GEMDOS is not GEM, it's more like BDOS in CP/M.

The XBIOS is an extension of the BIOS. The kernel supports the GEM (You can use it without GEM if you like). Even without GEM the TOS doesn't look like CPM/68k. Try to run an CPM program (of course from the TOS) und you'll see what happens...several bombs...reset....:-)

  The problem is that ATARI had the intention to use CPM (and told so) but changed their mind later on. But several M-magazines are still writing something about CPM68k on the ST. If they would have tried to run an CPM program the would have known better.

Finally, I'm not the ultimate source for such informations, I know some facts but not all...feel free to revise the above.

Keywords: Atari ST monochrome monitor

The Atari ST's monochrome video is *not* interlaced. It runs at 71hz.
It was done this way so the screen would look good.

The color display runs at 50hz or 60hz depending on the setting of
the PAL/NTSC bit in the shifter configuration register.

Book Review: Atari ST GEM Programmer's Reference
Authors: Norbert Szczepnowski and Bernd Gunther
Publisher: Abacus Software
Price: $19.95

Short review: This is what the developer's kit should have included.

Long review:

    This book bills itself as "The complete guide to programming the ST
using the Graphics Environment Manager," and it is not too far off the
mark. As with all of its predecessors, it starts off with the obligatory
heaping of praise on the Motorola MC 68000 and the ST. The book is about
400 pages long, and is divided into four chapters: GEM Organization in
the Atari ST; Programming with GEM; Inside GEM -- the VDI; and Inside GEM --
the AES. Unlike "ST Internals," this book has an index. There are three
appendices: Overview of the VDI Functions; Overview of the AES Functions;
and the ever-popular 68000 Instructions.

Chapter 1: GEM Organization in the Atari ST

This chapter is a very short description of the interactions of the components of GEM, and contains little usable information. A description of the limited multi-tasking ability of the ST is given.

Chapter 2: Programming with GEM

Another title for this chapter might well be "How to use your developer's kit." This chapter starts off with a short intro to C (I recommend sticking with Kernighan and Ritchie) and branches off to assembly language. As with the Internals book, this book reflects the early developer systems which included MINCE as the editor, and a short tutorial for MINCE is provided. The individual programs that make up the C compiler are discussed (without information about flags, if any) as is the AS68 assembler. In all, this chapter is a bit dated, but might be helpful to someone who has just gotten their kit.

Chapter 3: Inside GEM -- the VDI

This chapter presents an Atari ST specific version of the VDI routines. The VDI functions are divided by type (control, output, graphic, etc.) and each description provides a summary of the input and output parameters and a description of what they do. The C type declarations and binding is provided, and is followed by ST-specific remarks. Where applicable, examples of the graphics output are shown. The chapter ends with several examples coded in both C and assembler. Many of these examples would appear to be easily incorporated in other programs.

Chapter 4: Inside GEM -- the AES

In this chapter the AES is described in the same manner as the VDI is described in chapter 3. Many of the concepts are presented in a slightly easier to understand form than the developer's kit. The various types of buttons are quite well described. The method of defining structures for use with the dialog boxes is quite nice, providing an easy alternative to the Resource Construction Set. Unfortunately, the RCS is not covered in this book. Once again, the chapter ends with some rather nice examples in both C and assembler.

Summary

"Atari ST GEM Programmer's Reference" provides a reasonably complete discussion of programming in the GEM environment. This book is a nice addition to the documentation in the developer's kit, and would provide an excellent source for those who wish to program the ST but don't have the kit. Together with "Atari ST Internals," most of the useful information given in the developer's kit can be found, and found more easily. I would highly recommend this book; it's only failing is the lack of documentation on the Resource Construction Set.

Standard disclaimers about opinions above not representing, and my not working, etc. etc.

Does any one out there know how to use the 6x6 system font in GEM programs? I tried using vst_font with all types of values, but I kept getting back the standard 8x8 font.

In a similar question, is there a font editor available? And even if not, if I create a font in the proper format, what do I have to do to load and use it?

Thanks,

--- Bri
